Bilingualism and Youth Language

MARGREET DORLEIJN AND JACOMINE NORTIER

Terminology

In this contribution we will give an introduction to the linguistic behavior of young people in ethnically mixed groups, often referred to as youth language or multiethnolects.

Many relatively recent immigrant communities of various ethnic and linguistic descent have settled in large urban centers all over Europe. In these communities, very specific slang-like linguistic varieties pop up among urban, multiethnic adolescent groups. These varieties are often referred to by the general public as “youth slang,” “language of the street,” “youth language,” and so forth. In the sociolinguistic literature they are generally labelled as “multiethnolects.” In recent decades, the phenomenon of these “multiethnolects” has received the warm attention of sociolinguists. These youth varieties (or rather, styles—see discussion below) share remarkably many features and characteristics, whether they are spoken in Scandinavia, the UK, the Netherlands, and so on. In this contribution, we use the term multiethnolect, although we are aware of its problematic status.

Although there is much debate among researchers about the precise nature of the phenomenon, a majority seems to be comfortable with a definition like the following (taken from Dorleijn & Nortier, in press):

a linguistic style and/or variety that is part of linguistic practices of speakers of more than two different ethnic and (by consequence) linguistic backgrounds, and contains features from more than one language, but has one clear base-language, generally the dominant language of the society where the multi-ethnolect is in use.

In the literature, there is an ongoing discussion about the (correct) use of the term: there is no static set of linguistic norms, nor a one-to-one relation with specific ethnic groups. For a more detailed discussion see Jørgensen (2008) and Nortier (2008). It is tempting to attribute the recent warm attention of sociolinguists to the fact that multiethnolects have emerged only recently, in the wake of migration waves toward Western urban areas; that they are, in fact, a logical product of late modernity. This, however, is unlikely, since migration has happened all over the world, and the presence of multiethnic urban areas are a global phenomenon too. Multiethnolects certainly exist outside the Western world, as one can infer from work by, for instance, Kießling and Mous (2004) on African urban youth languages.

Moreover, multiethnolects appear not to be such recent phenomena. For example, Wolfram already reports in 1974 on Puerto Rican American groups where, as Fought (2006) formulates it: “adolescents in particular have been found to use certain features of AAVE [African American Vernacular English] in their English” (p. 450).

We see a multiethnolect as one of the possible outcomes of crossing, which was first described by Rampton (1995). In crossing, elements from other languages than one’s own are used to construct a (new) identity. With the term multiethnolect, however, we refer to more than crossing, as the term is also supposed to cover language play or manipulation. An example is given below to illustrate how people who use *verlan* (France) play with words by turning them upside down and use elements from languages other than French at the same time.

Function of Multiethnolects

As was noted above, multiethnolects are typically used by speakers of diverse ethnic backgrounds, and this includes the dominant, mainstream background. Multiethnolects appear to be a mostly urban phenomenon that emerges among adolescents in a context of migration in cities. This is not surprising: Multiethnolect users are much involved in the process of constructing and presenting a social identity, and such actions are an unavoidable consequence of living in the highly dynamic circumstances that multiethnic neighborhoods in large urban areas provide.

For adolescents in these circumstances the culture of the home is but one of many possibilities on which to build an identity. Both migrant and nonmigrant adolescents are invited to embark on a quest through a landscape with all kinds of linguistic and cultural possibilities but no clear directions, no obvious dominant tendencies, no fixed social positions. Therefore, an appeal is made to their own creativity in designing a desirable identity, and that is exactly what the multiethnolect is used for. These uncertain but (linguistically) rich circumstances leave people with all kinds of linguistic possibilities to create new, multicultural identities. Since multiethnolects are used in highly dynamic circumstances and mainly by adolescents, the exact form of the lects is not very stable and they are in most cases probably ephemeral. The degree to which multiethnolects persist when the users assume responsibilities for family and career needs further investigation.

Multiethnolects should therefore not be considered as clear-cut, stable *varieties* of a language, but rather as *styles*. "Style" or "linguistic style" is a complicated topic in which several dimensions play a role (see, e.g., Eckert & Rickford, 2001; Auer, 2007; Coupland, 2007; Keim, 2007; Quist, 2008). What concerns us here is that linguistic style can be mobilized by speakers in the appropriate situation, and can be associated with specific situations, interlocutors, or interaction types. Style, in the definition of Eckert (2001), is a "clustering of linguistic resources and an association of that clustering with social meaning" (p. 123). A style is used in particular circumstances or with particular interlocutors. The term "multiethnic style" would therefore have been a more appropriate term in this respect. The term is used for in-group communication. As with speech styles in general, speaking a multiethnolect means a continuous act of identity, a way of self-positioning versus the out-group and toward consolidating in-group solidarity. The literature reports that the kind of social identity multiethnolect users wish to convey is fairly universally a tough, "gang-like," "street" identity, and is generally associated with non linguistic stylization such as clothing and musical preference.

Linguistic Features of Multiethnolects

As indicated above, multiethnolects have in general one base language, which is usually the dominant national language of the country. In countries where more than one official language is spoken, more base languages are generally involved. Into the base language, features of other languages are mixed. "Mixing" occurs on all linguistic levels: phonological, morphological, lexical, syntactic, and, very prominently, in prosody and intonation. Linguistic characteristics that are attested in many multiethnolects are

- exaggerated and consciously stereotyped features characteristic of second language learners (grammatical structures, pronunciation, prosodic features);
- insertions of (non-dominant-language) formulaic expressions, greetings, discourse particles, all kinds of interjections, (taboo) content words and even occasionally function words of diverse linguistic sources; and
- word reversion (in some multiethnolects).

These characteristics are (mainly) the result of conscious agentivity by multiethnolect users, and they always carry social meaning, as may be illustrated by the following interview fragment (taken from Nortier & Dorleijn, 2008):

- (1) R: Dat is het slechte Nederlands
 I: En heeft dat ook een naam?
 R: Ja, niet echt, maar 't is in principe dan eh lidwoorden die gebruik je dan expres verkeerd.
 I: Ja, ja, die gebruik je dan *expres* verkeerd, net als—
 R: Ja dus
 I: Die *meisje*
 R: Die huis zeg ik dan. Terwijl ik weet ik bedoel ik weet heus wel dat het dat huis is, maar 't staat zo dom als ik dat op straat zeg, als ik zeg
 I: Ja
 R: Als ik zeg dat huis
 I: Jaja
 R: 't Is gewoon die huis. Maar als ik met jullie spreek dan wordt 't gewoon dat huis.
 R: That is the bad kind of Dutch
 I: Does it have a name?
 R: No, not really, but in principle you uhhh . . . just use the articles deliberately in the wrong way.
 I: Right! So you use them in the wrong way deliberately? Just like—
 R: Yes, like
 I: *Die meisje* ['that girl'—*dat meisje* in standard Dutch]
 R: I would say *Die huis* ['that house'—*dat huis* in standard Dutch]. At the same time I know, I mean, I am very well aware of the fact that it should actually be *het huis*, but it would make a stupid impression if I would say . . .
 I: Yes
 R: If I would say *dat huis* out on the street
 I: Yes, yes
 R: It is just *die huis*. But when I speak with you [the authors—both Dutch and middle-aged] it is just *dat huis*.

In many cases, elements from one (of several) contributing languages are more manifest than elements from the other languages. In a Dutch multiethnolect, for instance, features from Moroccan languages are more predominant than elements from other contributing languages, such as Turkish. Similarly, Turkish is predominant in German multiethnolects (see, e.g., Dirim & Auer, 2004). This may partly be due to the fact that speakers of such a language constitute a majority within the multiethnolect speaking group, but this is not necessarily the only factor. It is also likely that the speakers of the language that predominantly provides “ethnic” elements have a certain covert prestige compared to other “ethnic” groups, that is, they are considered to be “tough.” For example, in the Netherlands, respondents repeatedly have maintained that Moroccans are tough and Turks are dull (own field notes).

Other factors of importance that contribute to the actual structural and formal manifestation of a multiethnolect are sociolinguistic tendencies like language maintenance and shift, degree of multilingualism, and so on. For example, the above-mentioned Dutch multiethnolect (Dorleijn & Nortier, 2008; Nortier & Dorleijn, 2008) draws in particular from Moroccan resources, rather than, for instance, from Turkish, even though these communities in the Netherlands are comparable in terms of size and cultural background. Here, it

is the sociolinguistic situation of the communities in question that differs considerably and make the Moroccan elements more “adoption-prone.” Beside Dutch, two home languages are spoken in the Dutch–Moroccan community: Moroccan Arabic and Berber. An estimated 70% of the Moroccans living in the Netherlands are Berber speaking. Although most Berber-speaking Moroccans are more or less familiar with Moroccan Arabic, this does not imply that every Berber speaks Moroccan Arabic fluently. Therefore, Dutch is often the unmarked mode within the community. In the close-knit Turkish community in the Netherlands, on the other hand, Turkish is still very vital. The unmarked mode among Dutch–Turkish bilinguals is the bilingual code switching mode, which is considered an in-group mode by its speakers (and by outsiders, who often complain that they feel excluded in all-Turkish company; see Nortier & Dorleijn, 2008).

Examples

The way groups of young people in ethnically mixed groups use linguistic resources to express their identity is not the same for all groups everywhere. What the groups do have in common is that they include languages other than the official prestigious languages, and that the varieties they use are in a continuous state of change.

In Germanic-speaking countries in Europe and in America, where the phenomenon has been relatively well studied in the past decades, multiethnolects are varieties based on the official languages. They are “a kind of Dutch” (or Norwegian, German, etc.) rather than a mix of languages. The users of multiethnolects have a native (or native-like) control of the official language which constitutes a firm base into which they insert additional elements from other languages. In languages other than English, (American) English is an important source too, since it is associated with prestige and fashion. A quote from Nortier and Dorleijn (2008, p. 138) underlines this statement: “Nederlandse taal klinkt gewoon niet, dat Marokkaans accent zorgt ervoor dat het ‘rap-achtig’ wordt net als in de Bronx NY” (“Dutch just doesn’t sound good, that Moroccan accent makes it sound more ‘rap-like’ just like in the Bronx NY”). In recent years, we have found many examples of Dutch pronounced with a Moroccan accent in the Netherlands. In other languages such as German, pronunciation also is used as an ethnic marker (Deppermann, 2007, p. 329):

- (2) Hab **isch** gekauft neue BMW
 Standard German: ich habe einen neuen BMW gekauft
 ‘I bought a new BMW.’

In (2) *ich* ‘I’ is pronounced as slightly fronted palatal *isch*, which marks an ethnic identity and has its roots in the pronunciation of German by native speakers of Turkish. This form is also used by speakers who do not know any Turkish, and it is frequently heard in popular rap songs, for instance.

Other markers are syntactic or morphological in nature. An example is (2) above: The German word order SVO/SOV is violated here and, instead, VSO is used. Word-order violation is also found in, for example, language use by native speakers of Norwegian. In (3), the SV order is used in a sentence that requires inversion (Svendsen & Røyneland, 2008, p. 75):

- (3) hvis en av oss vinner vi deler halvparten
 ‘If one of us wins *we split* half’ (instead of correct Norwegian *split we*).

Violations of standard word order are typically associated with an imperfect second language acquisition. The speakers under consideration, however, speak the target language well and in unmarked communication they usually have no problems with the canonical word order (though exceptions to this rule do occur).

In languages with a grammatical gender distinction such as Dutch, German, and the Scandinavian languages, the use of a wrong grammatical gender is often encountered in multiethnolects. This was illustrated in example (1) above, where the speaker explained that he deliberately used the wrong gender when he was talking to his friends informally. In Dutch and other languages, the common gender is often overgeneralized and also used for neuter words: Swedish *en bord* is used instead of the correct *ett bord* 'a table' (Kotsinas, 1998).

In example (4) from Cutler (2008, p. 15), an 18-year-old Bulgarian who emigrated to the USA at age 8 uses characteristics of African American Vernacular English (AAVE) in relation to both pronunciation and grammar:

- (4) She is PISSIN' me off! All the shit she's sayin'. I [a:] feel like smackin' 'em. I'm like "Ø you stupid? Do you hear what you're (r-Ø) saying"? (..) She Ø mad racist! (...)

In the example above, typical AAVE features are monophthongal /a/ instead of /ay/, /r/-lessness, Ø-copula, and the use of *mad* as an intensifier.

In French, and in some other Romance languages such as Spanish, varieties have emerged in which lexical elements (words, syllables, or both) are reversed. So, for example, instead of French *cit  * 'city', *t  ci* is used. This variety, *verlan*, is widespread in France and emerged in the *banlieues* (suburbs) of Paris and other major cities among multiethnic youth groups. Beside the reversed use of words and syllables, there are other characteristics, illustrated in a poem in *verlan* in (5) (Didaweb, 2010; left column). An explanation of the *verlan* forms is given in the center column, and a translation into English on the right:

(5)		
J'neco ap La Marseillaise	J'neco ap = je ne connais pas la Marseillaise = French national anthem	I don't know La Marseillaise
Mais c'est ici que je mange mes fraises		But I belong here
Au debl��, j'suis c��fran	debl�� = bled	Back home I am French
Et j'suis robeu en cefran	c��fran = fran��ais robeu = beur (= arabe) cefran = France	And here I am an Arab
K��blo entre ici et l��-bas	k��blo = bloqu��	Blocked between here and there
Des fois j'ai envie de me s��ca	s��ca = cass�� (j'ai envie de partir)	Sometimes I feel like leaving
Mais c'est pr��s d'Paris qu'j'ai grandi		But I grew up near Paris
Et l'Alg��rie j'l'ai tchav' quand j'��tais p'tit	tchav' = quitt��	And I left Algeria when I was small
Alors o�� j'me v��trou?	v��trou = trouve	So where do I find myself?
J'me sens perdu, c'est chelou	chelou = louche	I feel lost, it is bizarre
Fiert�� d'��tre un djez �� Paris	un djez = un Alg��rien	Proud of being an Algerian in Paris
Tous les soirs, c'est Allah que je prie.		Every night I pray to Allah.

Examples of longstanding ethnic mixing (at least, in comparison with Western Europe) can be found in African cities where a long tradition of urbanization and migration has interesting linguistic consequences. Contrary to the varieties found in European cities, the varieties in African cities do not always consist of one clear-cut and recognizable base language in which elements from other languages are inserted. Slabbert (1994) describes the situation in Johannesburg where Isicamto is spoken, which is associated with a gang with a Zulu background. It has traces from Zulu, English, and a range of other languages. Isicamto started out as an urban youth language, but is spreading now to other groups as well. Consider example (6):

- (6) If u-roof-a i-bank ya-se-lokishi-ni u-ya-tabalaza?
'If you rob a bank in the townships, is that fighting for survival?'

The word *roof* has roots in Afrikaans; *bank* is English; *lokishi* is from English 'location' and *tabalaza* has its origins in Zulu (*zabalaza* 'struggle').

Conclusion

Multiethnolects have emerged all over the world and will continue to do so. Young people have always used linguistic resources to express their identity. They have always turned to varieties with strong covert prestige and low overt prestige. In places where there is no ethnic mixing, other substandard varieties and dialects are used for this purpose. With the arrival of other ethnic groups, other languages and varieties have become available and are made use of. As globalization increases, and movements such as migration and urbanization increase accordingly, we expect the emergence of new multiethnolects to increase as well. Linguists and anthropologists should study the spread of these varieties, not only among young people but also among other groups in many different societies. We still do not know much about the mechanisms that cause the difference between multiethnolects in the Western world (one base language) and beyond (such as in Africa, multilanguage based). More explorative and comparative research is needed. We believe that the more a multiethnolect will spread, the stronger the need for groups of young people will be to "invent" new ways of speaking to distinguish themselves from others.

Blum-Kulka, Shoshana

ZOHAR KAMPF

Blum-Kulka is Professor Emerita at the Hebrew University, Jerusalem, specializing in pragmatics and discourse analysis. Her pioneer contributions to the fields of translation, cross-cultural pragmatics, pragmatic development, interlanguage pragmatics, language education, family discourse, peer discourse, and media discourse assisted in establishing the methodological and theoretical basis of applied linguistics. The discourse pragmatic approach, developed in her theoretical and empirical studies, made an important contribution to the field of linguistic pragmatics, helping to refute claims of the presumably monological nature of pragmatic theory, and speech act theory in particular (Linnel, 1998).

Shoshana Blum-Kulka was born in 1936 in the city of Cluj, Transylvania (then Romania, taken over by Hungary in 1940). Following the Nazi occupation of Hungary in 1944, she escaped on what is known as the “Kastner train” with 1,683 other Jews. Blum-Kulka arrived in Israel at the age of 9 and was educated at the Hebrew Reali School of Haifa. She earned a BA in English Literature and Romance Languages at the Hebrew University in Jerusalem and a Master’s in Education from Teachers College, Columbia University in New York. She continued her academic studies back at the Hebrew University in Jerusalem, earning a PhD in Hebrew Linguistics under the supervision of Chaim Rabin in 1974. Prior to pursuing a full-time career as a scholar, Blum-Kulka ran the Intensive Hebrew Language Program for Overseas Students at the Hebrew University for 10 years, and was involved in writing and editing several textbooks of teaching Hebrew as a second language. She is credited with having introduced new approaches (both communicative and structurally graded) to the teaching of Hebrew as a second language, which subsequently completely transformed the way L2 is taught at university level in Israel. She began her academic career as a lecturer at the Center of Applied Linguistics at the Hebrew University in 1974 and was later invited to join the Department of Communication and the School of Education at the same university, where she served as professor of communication and education until her retirement in 2004.

From her early research on speech acts across cultures to her latest research on the dialogic and intersubjective nature of communication, Blum-Kulka promoted two basic ideas that establish the range and vision of applied linguistics: language use as social action and language use as a process of meaning making. Blum-Kulka’s contribution to the field of applied linguistics in the late 1970s took several forms: her dissertation on linguistic simplification for language learners, textbooks for teaching Hebrew as L2, articles on principles and methods of language teaching, pragmatic studies of translation (e.g., 1982) and lexical simplification (Levenston & Blum-Kulka, 1978).

At the outset of the 1980s Blum-Kulka’s research expanded to cover cross-cultural pragmatics in addition to the study of pragmatic competence in a second language (interlanguage pragmatics). The well-known Cross-Cultural Speech Act Realization Project (CCSARP), headed by Blum-Kulka, Kasper, and House, integrated linguistics, speech act theory, and politeness theory in demonstrating cross-cultural and situational variation in the performance of requests and apologies (Blum-Kulka, Kasper, & House, 1989). This study provided the theoretical and methodological framework for the empirical study of speech acts across cultures, adding to the “armchair” or role-play methods used until then—a semi-structured

questionnaire (the Discourse Completion Test), which became widely popular for the quick collection of speech act data from large samples. Among the major contributions related to this project is Blum-Kulka's finding (1987) that different cultures exhibit diverse scales for the perception of politeness that do not conform to Brown and Levinson's equation of politeness with indirectness. This finding may be viewed as one of the first to challenge the universal claim of politeness theory.

Concurrently, in the mid-1980s, Blum-Kulka was also involved in studies of natural discourse, focusing on issues of (mis)understanding (with Weizman, 1988), and cultural ways of speaking in family discourse. These studies, which focused on the interactive nature of communication as a process of meaning making, were the basis for formulating her discourse pragmatic approach during the 1990s (e.g., 1997b). In her studies on family discourse she explored cross-cultural differences in natural family discourse at dinnertime between native Israelis, native Americans, and American immigrants in Israel. Blum-Kulka showed that family dinnertime, at least in the communities studied, share several basic characteristics related to the nature of the speech event, yet differ deeply in patterns of sociability and socialization, providing culturally distinct sites for children's pragmatic development (1997a). *Dinner Talk* was a major contribution to the study of pragmatic socialization in that it devoted close attention to the many-faceted contributions of multiparty, intergenerational talk for children's pragmatic development whereas other contemporary research tended to focus mainly on dyadic mother-child interaction. Further work along these lines showed the benefits of multiparty talk for pragmatic development across different cultures and genres (see Blum-Kulka & Snow, 2002). Best known from Blum-Kulka's work on specific genres are her studies on narratives, in which she developed a three-dimensional model (*telling, tales, and tellers*) to account for cultural variability in the unfolding of stories in conversation (e.g., 1993).

Blum-Kulka's interest in pragmatic development led her (by the mid-1990s) to the study of young child-child peer interactions in natural discourse, developing a theoretical view of peer talk as a "double opportunity space," which functions concurrently on the plane of meaning making within childhood culture as a locus for the co-construction of children's social world and peer culture, while at the same time affording opportunities for the development of discursive learning (e.g., 2005). Her studies of natural peer talk of preschool and preadolescent children demonstrate the cultural co-construction and discursive affordances for pragmatic development of peer talk in a gamut of genres, including casual conversation, narratives, explanations, pretend play, and argumentative talk (e.g., Hamo & Blum-Kulka, 2007).

Blum-Kulka's broad intellectual interests found further expression in her important contributions to the field of mediated political discourse. Her pioneer studies on political interviews (1983), and later on debates and talk shows (2001), made significant contributions to the contemporary field of broadcast talk. In her studies during the late 1990s and the 2000s Blum-Kulka integrated methods of conversation analysis, ethnographic observations, and pragmatic methods and theories, thus defining the methodological tool box used by scholars of discourse analysis (Tracy & Haspel, 2005).

To conclude, Blum-Kulka is among the first to introduce pragmatics to the field of applied linguistics, to develop an integrative approach (discursive pragmatics) to the study of language use, and to apply this approach innovatively and fruitfully to relatively understudied areas of interest, such as media discourse, family discourse, and, more recently, first- and second-language child peer talk.

Bowen, J. Donald

LYNN HENRICHSEN

J. Donald Bowen (1922–89) began his academic career as a Spanish teacher and researcher and became an early leader in applying the findings of modern linguistics (especially phonetics and phonology) to language teaching methods and procedures. He was a prominent pioneer in conducting contrastive analyses of English and Spanish. His greatest contribution, however, was probably in the area of pronunciation instruction (Bowen, 1972, 1975). His thinking about the importance of meaningful, contextualized pronunciation practice resulted in what is today called the “Bowen technique” (Celce-Murcia, Brinton, & Goodwin, 2010, pp. 9, 93, 147–8). The linguistic and instructional principles he championed influenced many pronunciation teachers and textbooks and even formed the basis for entire pronunciation courses (Henrichsen, Green, Nishitani, & Bagley, 1999). His linguistic and pedagogical expertise extended beyond pronunciation, however, to the entire range of language skills and corresponding instructional procedures. Throughout his life, Bowen was an acute observer of the way language was actually used and a tireless advocate for teaching “realistic English.”

For most of his academic career, Bowen was a professor of English as second language and applied linguistics at the University of California Los Angeles (UCLA), where he influenced many generations of teachers. In fact, his UCLA colleagues Marianne Celce-Murcia, Donna Brinton, and Janet Goodwin dedicated their monumental *Teaching Pronunciation* (2010) to him and his associate Clifford Prator, their “mentors in the teaching of pronunciation.” When Bowen passed away, the UCLA academic senate issued a statement in memoriam, calling him “a remarkable scholar and dedicated educator” who “strove to excel in his field and consequently made exceptional contributions in applied linguistics.” In a professional obituary and tribute published in the *TESOL Newsletter*, University of Pittsburgh professor, Edward Anthony (1989), praised Bowen’s “wide, deep, and long experience, and his thorough knowledge of language acquisition, language teaching and learning, testing and evaluation” and his “amazingly productive pedagogical life.”

Since the schools Bowen attended when growing up did not offer foreign-language coursework, he did not study any languages except English until enrolling at Brigham Young University. There, he earned his bachelor’s degree in English and Spanish and also took courses in French, German, Latin, and linguistics. While earning that degree, he was called to active duty in the US military in April 1943 and participated in the army specialized training program (ASTP), where he became interested in “modern” techniques for language instruction. The ASTP curriculum, designed by linguists and concentrating on the spoken language, had (according to Bowen’s biography, 2004) “a profound effect” on his later life. He went on to earn his master’s degree in Spanish from Columbia University in 1949 and his PhD from the University of New Mexico in 1952. His master’s thesis involved a linguistic analysis of *El Conde Lucanor*, and his doctoral dissertation examined “The Spanish of San Antonito, New Mexico” using the analytic and descriptive methods of linguistics. The rest of his life’s academic work also involved the application of linguistics to related fields.

Throughout his life, Bowen taught and traveled widely. Shortly after receiving his PhD in 1952, he participated in the Summer Institute of Linguistics in Bloomington, Indiana,

where he met Henry Lee Smith, director of the School of Languages at the Foreign Service Institute (FSI) in Washington, DC. Bowen started work at the FSI in June 1953 with the job title “scientific linguist” and taught foreign service and air force personnel assigned to posts in Latin America. As a linguist, Bowen supervised several native-speaker instructors, corrected students’ pronunciation, and provided grammar explanations. The FSI curriculum was intensive, relied heavily on descriptive linguistics, and emphasized pronunciation and intonation (which were often slighted in other language programs of the day). At this point in his career, Bowen began making plans to adapt the linguistics-based FSI approach to foreign-language teaching in traditional universities and other instructional settings.

The 1955 Modern Language Association (MLA) convention in Chicago turned out to be an important milestone in Bowen’s career. Language educators from around the country discussed the future of language teaching, and most agreed that changes needed to be made. The Rockefeller Foundation provided a grant, and a committee of six distinguished linguists was named to write a “new kind of college textbook.” After four years of labor, this team, Bolinger, Bowen, Brady, Haden, Poston, and Sacks, produced the landmark *Modern Spanish* (Bolinger et al., 1960), which became a model for a whole new generation of foreign-language textbooks.

In 1959, Bowen joined the faculty at UCLA, but during his 28 years at that university he spent many years away from Los Angeles. From 1959 to 1963, he served as codirector of the Philippine Center for Language Study (PCLS), a project funded by the Rockefeller Foundation and administered by UCLA, “dedicated to serving the interests of language research, study, and teaching in the Republic of the Philippines” (Dacanay & Bowen, 1963, p. ii). On his departure, his “progressive leadership” was lauded by Filipino officials as having “made a significant contribution to education in this country . . . by assisting in the preparation of linguistically oriented instructional materials [and] helping . . . find solutions to . . . complex language problems through research and experiments.” The PCLS was intended to be a model for similar operations elsewhere in the world, and Bowen also advised the Southeast Asia Treaty Organization (SEATO) when it was establishing its Regional English Language Center. Later he was appointed to the English Teaching Advisory Panel of the US Information Agency. In 1966, he served as a consultant in Uruguay and directed the first of many National Defense Education Act (NDEA) institutes in TESL at UCLA. That same year, he participated in a USAID study tour in India. In 1968, he moved to Ethiopia to serve as field director of the Ford Foundation’s five-country “Survey of Language Use and Language Teaching in Eastern Africa” project. In 1970 he went to Nairobi, Kenya in connection with the same project. In 1974–6, Bowen represented UCLA as a visiting professor at the American University and the Ain Shams University in Cairo, Egypt.

Besides all the work he did in these positions and international programs, Bowen authored or coauthored 38 books. Most noteworthy in the application of linguistics to language teaching were probably *Modern Spanish* (Bolinger et al., 1960), *Techniques and Procedures in Second Language Teaching* (Dacanay & Bowen, 1963), *The Sounds of English and Spanish* (Stockwell & Bowen, 1965), *The Grammatical Structures of English and Spanish* (Stockwell, Bowen, & Martin, 1965), *Patterns of English Pronunciation* (Bowen, 1975), *Adaptation in Language Teaching* (Madsen & Bowen, 1978), and *TESOL—Techniques and Procedures* (Bowen, Madsen, & Hilferty, 1985). He also edited *Beginning Tagalog: A Course for Speakers of English* (Bowen, 1965) and was on the editing committee of *Tagalog Reference Grammar* (Schachter & Otones, 1972). In the area of sociolinguistics, he coauthored *Language in Ethiopia* (Bender, Bowen, Cooper, & Ferguson, 1976) and *Studies in Southwest Spanish* (Bowen & Ornstein-Galicia, 1976). He also edited *Current Trends in Linguistics: Linguistics in Oceania* (Bowen, Dyen, Grace, & Wurm, 1971). At the time of his passing, he was working on the manuscript of yet another book. In addition to these books, he published over a hundred research articles.

Bowen was also an active contributor to many professional and academic organizations, such as the Modern Language Association. He joined TESOL (Teachers of English to Speakers of Other Languages) in 1967, the year after it was founded. For many years, he served as TESOL book review editor for the *Modern Language Journal*.

Bowen died at age 66 after suffering with Parkinson's disease for 17 years.

Brain Activity During Second Language Processing (ERP)

D. J. DAVIDSON

Overview

The electroencephalogram (EEG) offers a unique view of second language (L2) processing because it is one of the few noninvasive techniques available within cognitive neuroscience to directly examine brain function during key events that take place during language comprehension. An EEG recording is a record of large-scale electrical activity of the brain over time, usually recorded with an electrode attached to the skin on the scalp. Primarily because it offers good time resolution, and because it is somewhat better suited to receptive language processing rather than production, researchers have used EEG to address questions about the functional organization of second language (L2) comprehension and learning. The time resolution of EEG enables it to capture the rapidly changing electrical response to individual words, morphemes, or speech sounds. Because of this, experiments are often conducted to examine first and/or second language performance using tasks that require listeners (or readers) to comprehend relatively short-duration material such as syllables, words, or sentences. The average response is then used, for example, to better understand when or how L1 and L2 language processing differ in the first few moments after the onset of a word, and also how these responses change over time during learning.

A related technique is magnetoencephalography (MEG), which records a signal that is the magnetic counterpart to the EEG. Because of the properties of magnetic fields with respect to the skull, it is in many cases simpler to relate the MEG to the underlying cortical regions that are active in an experiment, compared to EEG. For this reason MEG is often used in conjunction with anatomical information available using magnetic resonance imaging (MRI) to provide spatial information about the source of the electrical activity. Although there are important differences between EEG and MEG, this entry will largely focus on EEG, as it is by far the most commonly used approach for L2 research to date. After a brief introduction, this entry will provide an overview of some of the major findings that have accumulated in the literature on L2 electrophysiology.

Basis of the EEG and ERP Signal

The EEG Signal

Neurons communicate with each other via complex electrical-chemical processes at a very small spatial scale relative to the size of an EEG electrode, and this raises the question: What does the scalp-recorded EEG signal actually represent? As a first approximation, the EEG is believed to be a large-scale measure that reflects the spatial alignment and temporally synchronous activity of groups of a certain types of neurons, with the largest contribution from pyramidal cells. When these cells are active together in time, the electrical potential generated is large enough to be recorded with an external electrode on the skin, with respect to a reference electrode at a different location also on the skin. In the case that cells

within the group are not synchronously active for a long enough period of time to sum, then the group activity will not be large enough to be observed, even if some individual cells are very active for shorter periods of time. For example, rapid events such as individual spikes from action potentials are not usually seen in EEG recordings under ordinary recording procedures. Also, if groups of neurons lack a parallel spatial orientation, an external sensor would not easily register their activity, whether or not it is synchronous. The EEG is therefore a selective measure of cortical electrical activity. It represents a certain timescale of activity from cells in a specific spatial arrangement. An important implication of this selectivity is that many important electrical events are almost certainly missed by the EEG recordings.

These considerations are probably most important for work that explicitly tries to link physiological processes in neurons and the cognitive operations that are believed to occur during (L2) listening or reading. Most studies of L2 processing, however, use EEG recordings more heuristically, as a gross measure of electrical activity without very specific assumptions about the link. These measures of electrical activity are termed components, which are spatial and temporal patterns of activity across the array of electrodes on the scalp. As an aside, it is good to bear in mind that in most recording arrangements the activity recorded with EEG is a difference between a given electrode and a reference electrode, thus reflecting activity measured at both sensors. Very often the reference electrode for EEG is placed in a standard location, such as behind one of the ears, or the nose, to make it easier to compare studies.

Before describing the components, it is worth describing a few common features of psycholinguistic experiments using electrophysiology. Very often, participants in an experiment listen to or read stimuli presented over a series of trials. Each trial is simply the presentation of a single stimulus, such as a word or a sentence, possibly followed by a motor response if participants are asked to make a judgment or decision about the stimulus. Usually, there are one or more different experimental conditions to be compared, and there are multiple occurrences of a single type of trial in the same experimental condition. For example, an experiment examining spoken word recognition might examine L1 and L2 word recognition by comparing the response to L1 words on some trials and L2 words on other trials. The reason for the multiple trials is that EEG recordings are subject to a great deal of noise or otherwise ongoing but unrelated brain activity, and a more consistent measure of the brain activity that is related to the stimulus can be obtained by repeating a given experimental condition many times. This does not mean that exactly the same stimulus is repeated (necessarily), but rather the experimental condition is repeated with a different word or sentence on each trial. For example, in the example for auditory word recognition, there might be 80 distinct L1 words presented versus 80 distinct L2 words presented in the experiment.

Event-Related Potential (ERP)

The most common measure (or model) for brain activity in L2 electrophysiology is the event-related potential (ERP). This is simply the average response in a group of trials recorded in a given experimental condition, where the average is calculated for each moment in time after the onset of the stimulus (or, in some cases, before a motor response). The ERP is a summary statistic because it uses a single time series, the average, to represent the important properties of the response for the entire group of trials. An assumption of this statistic is that the brain response to the stimulus reoccurs at a consistent time after the onset of the stimulus, and that other activity without this consistent timing is noise or unrelated activity.

Before taking the average, researchers typically subtract a baseline from the response to reduce the impact of variation that is considered noise. Alternatively, a high-pass filter

might be applied to the data. The baseline is usually defined as a short interval of time before the onset of a stimulus. The average value of the potential in this baseline interval is then subtracted from each point in the response interval. For this reason the baselined ERP often appears as positive or negative deflections from the zero potential, appearing very often as a dampened sinusoidal waveform. It should be kept in mind, however, that the actual average potential in the baseline time interval is not necessarily zero; it simply appears this way because of the baselining procedure.

The ERP waveform is usually described in terms of its features: the timing and magnitude of the most salient features of the waveform. The first few positive and negative deflections, occurring at approximately 100 ms and 200 ms respectively, might be termed the N100 and P200 components, for example, reflecting the polarity (N for negative potential, P for positive potential) and the approximate latency (e.g., 100 ms) of the peak of the component. Other components are named similarly, sometimes with designators to describe the general spatial location of the component on the electrode array. Two of the most important features of the ERP are the amplitude relative to the zero potential baseline, and second, the latency of a peak of a component (the point with the highest amplitude when there is clearly a single peak), relative to an event like word onset. These features have been shown to be responsive to several variables which are related to L2 language performance. Note that other summary statistics reflecting other aspects of brain activity, such as the average event-related time-frequency spectrum, or the average phase spectrum, can also be calculated from EEG data. However, their use in L2 research has not been widespread to date.

When one waveform in a condition is subtracted from another waveform in a different condition, the result is a difference waveform. It reflects time points when the two ERP waveforms diverge from each other. Many classical ERP effects are difference waveforms in this respect. Several typical effects seen in response to spoken or written words include the N400 effect, a negative potential difference wave beginning at approximately 300 ms and peaking at approximately 400 ms after word onset, and the P600 difference wave, a positive potential difference wave which begins at approximately 500 ms after word onset, and appears as a long-lasting shift, often without a single peak. In many experiments the N400 effect amplitude is responsive to the semantic relationships within the sentence. The P600 effect is likewise responsive to syntactic relationships within the sentence in many cases. It is also the case that many studies show a posterior distribution of both of these patterns. This means that the electrodes where the N400 or P600 difference waves are largest tend to be at the back part of the head. The timing, the polarity, and the approximate spatial focus of the difference wave are diagnostic features employed by almost all ERP studies of L2 (and L1) linguistic processing. Note that these patterns are general trends across studies, but there are important cases in which the N400 effect is seen in response to a syntactic contrast, and the P600 effect is seen in response to a semantic contrast. Another difference wave that has been important in studies of morphology or grammar is the left anterior negativity (LAN) effect, a negative difference wave appearing in approximately the same time window as the N400 effect, but with a left frontal focus on the scalp electrodes.

Properties of the ERP

There are several reasons why the features of the ERP waveform are used. The relatively high time resolution allows researchers to isolate a brain response with short duration. For example, spoken sentences unfold over time, and a given word might not have a duration longer than half a second. The ERP can reflect responses that occur within a few hundreds of milliseconds following a stimulus, therefore can reflect activity that is specific to a given word within the sentence in many circumstances. It is worth noting, however,

that the response to individual words within a sentence often overlaps from one word to the next, and the degree of overlap will depend on the rate of speech or the presentation rate of the stimuli more generally. For this reason, some studies use serially presented words with a relatively slow rate of visual presentation to artificially separate the response to individual words. It does not appear that there is a consensus in the literature about the side effects of the different modes of stimulus presentation, but both auditory and serial visual presentation remain in use.

Longitudinal and Group Comparisons

In L2 research, often experiments compare the ERPs of different groups of participants to investigate a question. Some examples include comparisons such as monolingual versus multilingual subjects, or early-acquisition versus late-acquisition learners. In these cases, the participants are selected for the study so that the groups are approximately matched on characteristics such as age, gender, handedness, and other factors that are likely to affect the results. This is done so that a comparison of the groups is likely to reveal only the influence of the factor which differentiates the groups (e.g., early versus late acquisition) and not other known factors. However, it is often the case that one of the groups is more variable than the other in their response, and it is difficult to distinguish systematic group variation from individual subject variation. Also, when participants are selected for a study, it is possible that preexisting differences might influence the pattern seen in an experiment.

One approach to this problem of individual variation is to examine the changing patterns of ERPs over time in a longitudinal study (Osterhout, McLaughlin, Kim, Greenwald, & Inoue, 2004). Whereas group comparisons characterize L2 speakers with differences in preexisting knowledge or experience, longitudinal studies track the acquisition (or development) of this knowledge over time. The longitudinal approach compares each participant against their own previous response to show a difference over time. In some cases this allows the design to factor out individual differences, especially when the learners in the longitudinal design start with little or no previous knowledge of the language they are learning. Longitudinal designs also characterize the dynamics of the changing ERP patterns, and this may be informative about how the knowledge is acquired.

Phonological Processes

Studies of sublexical L2 processing have for the most part employed a component known as the mismatch negativity (MMN). This component is seen during passive listening tasks in which listeners hear a series of standard stimuli (such as a phoneme or syllable), and an occasional mismatching stimulus. The mismatching stimulus elicits a larger amplitude waveform. This is believed to reflect the time when a cortical region registers the difference between standard and deviant stimuli. Studies of the MMN have shown that the effect can be seen in both younger and older L2 learners, but in the case that an L2 learner begins studying a second language relatively late, then the amplitude of the MMN is reduced for phonological contrasts in that L2.

Lexical and Morphological Processes

There have been many studies of the response to single words comparing L1 and L2 stimuli. Most often studies have examined the N400 component, a negative potential component with a posterior spatial focus, peaking around 400 ms after the onset of a word. The N400 is affected by a wide variety of contextual relationships, including semantic

meaning or association when words are presented in pairs. Studies that have examined the N400 component have found that the contextual influence on the N400 is similar in the L1 and L2, but also that L2 proficiency has an important influence. Lower L2 proficiency is associated with a reduced semantic context effect, but not a reduced associative context effect.

With respect to word morphology, differences between L1 and L2 speakers have been observed in processing inflectional morphology. For example, Hahne, Mueller, and Clahsen (2006) have found that overapplication of an inflectional plural rule for nouns results in only a P600 in L2 learners, in contrast to both a LAN and P600 that has been found in native speakers. Contrasts of verbal inflection showed an anterior negativity in the learners as well as a P600. In their experiments, the misapplications of irregular morphology led to a distinct N400 response. These results suggest that the electrophysiological response to morphological violations in learners can appear in a form similar to that of native speakers.

Grammatical or Syntactic Processes

In studies of syntactic or grammatical processes, researchers have most often examined the response to a single word or morpheme, the so-called critical word, presented in the course of a sentence. In many studies, one sentence will contain a grammatical mistake or error at the critical word, and this is compared to a control sentence which is otherwise like the violation sentence except for the mistake. The interest of such studies is to examine when differences emerge in the response to the violation critical word relative to the control, and moreover, how these differences are related to L2 knowledge, skill, and development.

The classical components described earlier (LAN effect, P600 effect) have been examined in several L2–L1 pairs, at various levels of group proficiency. The appearance of the P600 effect seems to be modulated by proficiency and age of acquisition, and possibly the particular language pairs that are involved in the study. Bilinguals who begin acquisition of both languages relatively early show a P600, and it is also seen in learners who start an L2 relatively late but who are nonetheless proficient in the L2. It appears that the P600 is more likely to be seen in an L2 if the L2 is part of the same language family as the L1 (e.g., Germanic), which is also likely to be correlated with proficiency. It should be noted that not all studies have observed the P600 in L2 learners, as some results have shown atypical patterns of the P600. So far, the LAN effect, including the early LAN effect (ELAN), although it has been studied less extensively for L2 learners than the P600, appears to be less commonly reported in the literature. The ELAN has only been reported in the case of relatively proficient L2 users (Rossi, Gugler, Hahne, & Friederici, 2006). Recent experiments have examined patterns of ERPs with longitudinal designs. To date, no study has observed a LAN effect over time, but interestingly, an N400 has been reported in addition to the expected P600, as learners gain L2 proficiency (Osterhout et al., 2004).

Semantic Processes

Like single-word studies, semantic processing for L2 comprehenders has been examined in sentences using the relationship between a critical word and the preceding context. The same logic of comparison between a violation condition and a control condition is followed in this type of design, often comparing groups of learners with different backgrounds of experience or proficiency.

The results of these studies have shown that an N400 effect can be seen in sentence context for L2 users, and it has a similar spatial pattern in the first and second language

users in most studies. In some cases there is a delay in the peak of the N400 for the L2. Studies that have independently examined the contribution of age of acquisition and proficiency have shown that both contribute to the delay in the peak. There is some variability in the N400 effect seen across studies, as some have reported no difference while a few cases have reported a larger N400.

Other Uses of the ERP Methodology

A small number of studies have employed ERPs to examine L2 production (see Hanulová, Davidson, & Indefrey, *in press*, for review). In the case of production, an additional complication is that signal artifacts associated with muscle movements of the face and larynx make it difficult to study the production of full sentences. Researchers have instead concentrated on picture-naming tasks in which a single lexical term is to be produced to label an object. For example, Christoffels, Firk, and Schiller (2007) examined the first half second after the appearance of a picture, but before actual articulation, to study language switching in bilinguals. Among other findings, they showed that naming pictures in an L1 resulted in a more negative waveform than an L2 at approximately 375 to 475 ms after picture onset, which is a relatively late difference in some models of production. Guo and Peng (2007) used a different technique, a “go-no go task” in conjunction with picture naming, to study L2 production with an ERP effect known as the N200 effect. The go-no go task required participants either to make or withhold decisions about semantic or phonological properties of the to-be-produced picture names in the task. The N200 appears on trials where a response must be withheld in the go-no go task, and the assumption is that the response can only be withheld when there is enough information available during production to actually suppress it. This can be used, for example, to compare semantic versus phonological decisions during word production. By comparing the latency of the ERP effect for these two types of decisions, Guo and Peng (2007) found no difference in the latency difference between semantic and phonological N200s when comparing a native L1 group versus the L2 of a learner group (see also Hanulová *et al.*, *in press*). These findings seem to suggest that delays in L2 word naming might stem from differences in relatively late word-production processes.

Conclusions

Electrophysiological research is largely complementary to experiments that use behavioral techniques, in the sense that it provides more direct information about brain activity. Behavioral techniques such as response time or eye-tracking techniques are much simpler to use in experiments, but often require the arrangement of a specialized task for participants so that a behavioral response can be measured. In contrast, electrophysiological experiments do not necessarily require a behavioral task in many cases, as the EEG response directly reflects brain activity. As such, EEG studies are probably most useful for testing hypotheses about brain function, and their relationship to behavioral measures is an active research question.

The research reported to date on second language processing has so far not reported an electrophysiological effect that has not already been seen in studies of L1 processing, and a relatively common finding is that certain effects which are consistently observed in L1 users are less consistently observed in L2 users. The electrophysiological response to speech sounds and words appears to be qualitatively similar in L2 listeners and readers to that of the L1, with largely quantitative differences in the ERPs that have been reported. At the level of sentence processing, it appears that both syntactic and semantic violation effects

can be observed, but that syntactic violation responses are more variable than semantic effects. Age of acquisition and proficiency both seem to play a role in determining this variability, and the greater variability of the syntactic response would suggest that the grammatical system is more vulnerable to variation in the timing and intensity of input during acquisition or learning.

Brain Imaging Studies and Vocabulary

MICK RANDALL

Brain imaging studies, behavioral studies, and anatomical studies of brain lesions are the three principal methods of investigating the way the brain processes language. The advent of new technologies has greatly enhanced the ability to examine neural activity in the brain, and such studies can be used to provide neurophysiological evidence for insights deriving from behavioral and anatomical studies. Thus brain imaging studies are complementary to evidence from behavioral studies, from studies of brain lesions and aphasia, and from theories of language processing derived from linguistic studies.

In cognitive linguistics, connectionist models are important metaphors to explain language comprehension. Models of lexical semantics and storage such as spreading activation (Collins & Loftus, 1975) and networking (Bock & Levelt, 1994) are central to these metaphors. Brain imaging studies of vocabulary are providing important support for theoretical models based on neural networks.

We shall consider the technologies involved and the methodology of such studies as well as the general anatomy of the brain as regards language processing, and look at the findings of studies connected with vocabulary first with regard to first language and then with regard to bilingual processing.

Methodology

Imaging Techniques

Although a number of techniques exist for investigating brain activity, we shall deal with those which are most commonly used in investigating language processing and divide them into two broad categories: electrophysiological techniques and neuroimaging ("hemodynamic") techniques.

Electrophysiological techniques measure levels of electrical activity. They involve the placement of electrodes on to the scalp to measure electrical activity produced by groups of neurons during specific cognitive processes. It is assumed that such increased electrical activity represents increased neural activity. Electroencephalography (EEG) and magnetoencephalography (MEG) are two such techniques. Both have very high temporal resolution but relatively low spatial resolution. Information is gathered at two times after the activity: the N400 (300–400 ms) and the N600 (beginning at 500 ms).

Hemodynamic techniques do not measure electrical activity, but measure increased metabolic activity such as blood flow. They have relatively poor temporal resolution (i.e., they cannot measure changes in very short time periods) but they have good spatial resolution (i.e., they can pinpoint brain structures involved to within 2–3 mm). Positron emission tomography (PET), the first metabolic imaging method extensively employed, measures emissions from radioactively labeled chemicals that have been injected into the bloodstream. PET was used extensively for the diagnosis of brain damage following strokes and other brain traumas during the late 1980s and 1990s. However, the most common neuroimaging technique today is fMRI (functional magnetic resonance imaging), because it does not use

2 BRAIN IMAGING STUDIES AND VOCABULARY

intrusive techniques and has enhanced spatial resolution. fMRI measures the magnetic properties of hydrogen and oxygen atoms in oxygenated and deoxygenated blood. fMRI studies are often supplemented by other methods such as EEG, MEG, or even stimulation techniques (where electrical stimulation is used to inhibit the function of specific brain areas).

Procedures

The experimental procedures involved in PET and fMRI studies are based on a subtraction paradigm in which experimenters establish a baseline image of neural activity; for example, subjects looking at a simple “+” in the middle of a screen. The subject is then asked to perform a task (e.g., identify an object) and the baseline pattern is then subtracted from the pattern observed during the task. The experimental conditions are presented either in blocks (block design) or as single events (event-related protocols). The differences between the baseline pattern and the pattern under the experimental condition are assumed to indicate the neural resources involved in carrying out the task. Tasks vary from atomistic, carefully controlled tasks in which a single variable is changed, such as naming a picture, to wider holistic tasks, such as reading a passage in a book.

One criticism of such studies is that there is never only one set of neurons or areas involved in even the simplest tasks and thus results are difficult to interpret (for discussion see Aquire, 1996). In vocabulary studies to measure visual processing, for example, subjects may be asked whether two visual objects are the same, yet the experimenter cannot be sure that the subjects have not subconsciously named the objects and thus involve verbal processing.

Another criticism is that there is a great deal of activity within the brain, and the targeted areas are those which stand out against a great deal of “noise.” Thus, the pictures or information gained are actually based on statistics—the highlighted areas are statistically different from other surrounding areas—and thus depend on the statistical thresholds set by the experimenter. It is also necessary to note that not all brains are identical: significant numbers of people have language areas in the right as against the left hemispheres, and right-handed males are usually selected for investigation. Even allowing for this, results are often difficult to replicate and individual differences do exist.

Brain Anatomy

The areas of the brain involved in cognitive processing are described in relation to the cerebral cortex, which is the outermost layer of the brain and has a highly convoluted appearance. This structure is divided into four areas or “lobes”: the frontal, temporal, parietal, and occipital lobes (see Figure 1a) and the cerebellum. In brain imaging studies, reference is usually made relative to these areas, with the addition of the adjectives “superior” and “inferior” to indicate top and bottom, and “anterior” and “posterior” to indicate front and back. In addition to the lobes, reference is also made to different gyri (gyrus in the singular), that is, the “ridges” which run across the cerebral cortex and, which, along with the sulci (sulcus in the singular), the “valleys,” produce its convoluted appearance. Beneath the cortex lie a number of subcortical structures, the hippocampus and the cingulate cortex being the most important for language processing as they are concerned with memory, and the basal ganglia being involved in planning (see Figure 1b).

Another common neuroanatomical map divides the cortex into numbered areas, Brodmann’s areas (BAs). Brodmann, a German neuroanatomist, identified more than 40 areas involved in cognitive functions (see Figures 1a and 1b).

Figure 1b Brodmann's areas: medial view, showing subcortical structures (adapted from *Gray's Anatomy*)

Language Processing and Anatomical Findings

Lateralization

PET and ECG studies have provided neurophysiological evidence for the location of language functions in the left hemisphere. These studies have confirmed the importance of Broca's and Wernicke's areas, revealed by earlier neuroanatomical studies of aphasia. The role of left and right hemispheres can be illustrated by a study comparing object naming and object recognition carried out by Acres, Taylor, Moss, Stamatakis, and Tyler (2009). Verbal tasks correlated with partially overlapping left inferior and anterior temporal lobe areas, whereas the core regions involved in object recognition were those of the right inferior and anterior temporal lobe. However, it should be emphasized that studies show large areas of the brain active in language tasks, and that the areas which are identified by the subtractive methodology are those which differ statistically from neighboring regions.

Language Modularity: Broca's and Wernicke's areas

For many years it was believed that Broca's area (BAs 44, 45) was involved in phonological processing and speech production and Wernicke's area (BAs 22, 39) was primarily involved in understanding syntax and comprehension. However, fMRI studies have shown the situation to be much more complex. Recent evidence demonstrates that Broca's area also plays a significant role in language comprehension, and a number of neuroimaging studies have shown the involvement of Broca's area during the processing of complex sentences.

In a meta-analysis of 129 reports Vigneau et al. (2006) compared areas of activation in the cortex concerned with phonology, semantics, and sentence processing. They found that the patterns of activation are best explained by postulating three neurological networks concerned with phonological processing, semantic processing, and phonological working memory. The areas concerned with these functions include sections traditionally associated with Broca's and Wernicke's areas. Yet these areas do not deal exclusively with one function. Within the semantic field, these authors found seven identifiable clusters, only three of which were concerned with semantic tasks alone.

Parallel Distributed Processing

It is clear that neural processes are widely distributed. Cognitive scientists now accept that there are numerous areas involved in any linguistic task and it is impossible to associate specific language functions solely with specific anatomical areas. For example, the task of recalling words involves many areas, mainly, although not exclusively, located in the left hemisphere. This network includes the inferior temporal lobe, the inferior posterior parietal lobule, the premotor areas of the frontal lobe, the angular gyrus, and the supplementary motor area. These results would seem to support a parallel distributed processing model for language comprehension.

Spoken Versus Written Language

Many studies have investigated the mode of presentation (for a meta-analysis of word production see Indefrey & Levelt, 2004). These studies support the concept of a set of core structures involved in language processing acting as a neural network, and calling on other structures for modality-specific tasks. The core areas within the left hemisphere which are independent of modality are the inferior frontal gyrus (BAs 46, 47), the middle temporal gyrus (BA 21), the supramarginal gyrus (BA 40), and the angular gyrus (BA 39). In addition

to these core areas, auditory presentation is accompanied by extra activity at the primary auditory cortex (BAs 41, 42) and across the superior temporal gyrus bilaterally (BA 22), whereas printed sentences raised activation in the fusiform gyrus (BA 37).

Issues Concerned With Vocabulary

Word Recognition/Processing

There has been a great deal of interest in investigating the degree to which different brain structures are involved in the subprocesses of lexical storage, retrieval, and production. Studies have compared activity during tasks requiring phonological versus semantic processing. Such tasks include detecting rhymes versus detecting synonyms, counting syllables versus categorizing words, and reading/detecting pseudo-words (where the subjects say the word aloud) versus reading/detecting words (where subjects recognize the word silently). Lexico-semantic processing has been found to be associated with activity in the left middle and inferior temporal gyri (BAs 21, 20), the left inferior parietal region (BAs 40, 39), and the left superior prefrontal region (BA 46) in addition to the superior temporal regions (BA 22).

Word Learning

Another issue which has attracted attention is that of the differential resources used to make decisions when verbal associations are new or established. Generally, studies have found greater activation in the inferior frontal gyrus (BA 44) with pseudo-words than with real words, suggesting greater neural investment in the short-term memory with the former.

Item recognition, on the other hand, involves retrieval from episodic memory. The medial temporal lobe is thought to play a mediating role in lexical retrieval and in episodic memory encoding tasks. Achim, Bertrand, Montoya, Malla, and Lepage (2007) investigated these issues in a series of experiments in which subjects were required to make judgments on pairs of words which relied on item recognition or associative recognition. The study indicated that arbitrarily related associations revealed greater activation of the parahippocampal region (BA 36), the area strongly associated with memory and retrieval. In another study differences were seen between automatic semantic priming and strategic semantic priming. Subjects were asked to react quickly to presented word pairs as against being given time to think (Gold et al., 2006). The results suggested a three-stage lexical process involving automatic activation of semantic representations, retrieval of semantic representations, and inhibition of competitors. Such a procedure would be congruent with current connectionist views of language processing.

Word Frequency

Physical word properties, length, and frequency are processed in the same regions as other language items, although low-frequency words are associated with relatively greater activation in the left prefrontal cortex (BA 45), left fusiform gyrus (BA 37), and anterior cingulate gyrus (BA 24) (Chee, Westphal, Goh, Graham, & Song, 2003). The processing of complex words confirms the left temporal lobe (which includes Wernicke's area) as the site of word representation and the inferior frontal gyrus (which includes Broca's area) as the site of processing structural information. Thus, irregular verb inflections will be accessed directly, while regularly inflected words will be decomposed into stems and affixes.

Age of Acquisition of Words

fMRI studies have indicated an increased level of activation in the left inferior prefrontal cortex (BA 45) when making lexical decisions on early- versus late-acquired words. It appears that words early acquired automatically activate auditory representations and map on to semantics. Thus areas in the auditory cortex and the inferior portions of the temporal lobe are activated. However, processing late-learned words involves the analytical inferior prefrontal areas for more complex semantic retrieval and selection processes. In addition, late-learned words elicit activity in the fusiform gyrus (BA 37), which is thought to play a part in orthogonal analysis in the visual word form area. This suggests that late-learned items require more visual form processing than early-acquired words, which have more semantic interconnections and rely on auditory word representations. Overall, imaging studies suggest that late-learned words excite brain areas which involve more effortful processing perhaps related to declarative memory processes (Hernandez & Li, 2007).

Dual Route Reading

There have been numerous neuroimaging studies which have investigated the neurophysiological evidence to support either a dual or a single route for lexical access. In a meta-analysis of 35 fMRI and PET studies of word reading, Jobard, Crivello, and Tzourio-Mazoyer (2003) found common left-hemispherical areas involved in the reading of both words and non-words. In tasks which did not require grapheme-to-phoneme conversion (i.e., recognition of regular words), superior temporal areas (BA 22, included in Wernicke's area), the supramarginal gyrus (BA 40), and the left inferior frontal gyrus (BA 44, included in Broca's area) showed increased activation. In tasks requiring lexical and semantic word access, as with irregular words, additional activated areas included the so-called visual word form area (VWFA) located in the mid-fusiform gyrus (BA 37), the posterior middle temporal gyrus (BA 21), and part of the inferior frontal gyrus (BA 44). It would appear that there are separable areas concerned with lexical and sublexical procedures in word access, and that these areas work in collaboration to facilitate lexical access in different degrees depending on the necessity for grapheme-to-phoneme conversion.

The presence of separable lexical and sublexical processes was further corroborated in a study specifically designed to examine neural areas involved in spelling. Norton, Kovelman, and Petitto (2007) found increased activation involved in spelling regular words in the posterior superior temporal gyrus (BA 22), the area centrally involved in phonological processing. Irregular words, however, elicited greater activation over a variety of other language areas, in particular the inferior frontal gyrus (BA 37), which deconstructs the orthography, producing candidate words which are then submitted to the left inferior frontal gyrus, the bilateral middle temporal gyrus, and the left supramarginal gyrus for semantic verification, as might be predicted from parallel distributed processing models.

First and Second Languages

Another issue which has received attention is the question of how first and second languages (L1 and L2) are processed by the brain. The general finding of the majority of studies is that in bilingual tasks there are no differences in activation between the L1 and L2; both activate the same core language areas in the left frontal corpus (BAs 44, 45). This similarity in processing sites is even seen with Chinese-English bilinguals despite the large differences between the languages, especially between material presented in logographic and alphabetic scripts (Chee, Tan, & Thiel, 1999). The same study also found no differences of activated areas between languages learned early or late. However, many studies have shown differences in the level of activation of the different areas. This often depends on

whether the language was acquired early or late. For example, one study found differences in the level of activation in BA 44 and 45, with more activation of BA 44 for late multilinguals (Franceschini, Zappatore, & Nitsch, 2004), and age of acquisition versus proficiency has received considerable attention. A meta-analysis of imaging studies of bilingual language production indicated more extended activations for L2 speakers with low proficiency (Abutalebi & Green, 2007). Such findings might suggest, as with levels of lexical complexity above, more effortful processing of the less fluent and later-acquired language signaled by greater neural density or connectivity. It has been suggested that the extra resources with later-learned language could relate to the greater use of declarative memory (phonological analysis, for example), whereas languages learned early are more integrated into automatic semantic processing systems.

Issues such as the resources deployed in translation and language switching have also been investigated. A number of studies have identified increased activation in the left and right superior prefrontal cortex (BA 46), a region associated with task management, which would indicate the use of a supervisory mechanism during language switching tasks. One model which predicts the use of such a mechanism is that of inhibitory control (Green, 1998), in which competition is resolved by inhibiting the language which is not required in the task set, for example in naming pictures in either the more or less dominant language. Different bilingual neuroimaging studies have indicated activation of the anterior cingulate cortex (generally known for control of attention, conflict monitoring, and error detection), the basal ganglia (known for task selection), and the inferior parietal lobule (working memory) as well as the prefrontal cortex, suggesting that these areas cooperate in cognitive control of language production.

Thus, there would seem to be a consensus that there are common language areas involved in all language processing, whether in L1 or L2, and there would seem to be no evidence of separate lexical stores for the different languages. However, with improving spatial resolution offered by new technologies, differences are beginning to emerge in the degree of involvement of different areas in lexical access and retrieval in bilingual and multilingual tasks within the core language areas. Studies are also beginning to highlight the complex interplay between different areas of the brain, including areas concerned with general cognitive tasks, and it is this interplay which is likely to fuel future research in the area.

Brazil, David

RICHARD CAULDWELL

David Brazil (1925–1995) was the originator of *discourse intonation*—a distinctive approach to research into spontaneous speech and the teaching of pronunciation and intonation (see <http://www.speechinaction.com/Brazil.htm>). This approach has influenced research, teacher training, and classroom practice around the world. Publications influenced by his work started appearing in the 1980s, and continue to appear—they include Bradford (1988), Hewings and Goldstein (1993), Cauldwell (2002), and Gorsuch, Meyers, Pickering, and Griffiee (2010).

When he was 18 he joined the Royal Air Force and served in the latter years of World War II in Italy. He subsequently served for a time in India. On leaving the forces he took advantage of the opportunity to become trained as a teacher, and began teaching English in a number of schools around the United Kingdom. During this period he studied for a bachelor's degree at the University of London, which he obtained after six years of hard work.

He is perhaps best known for his association, which began in the 1960s, with the University of Birmingham. A new degree of Bachelor of Education had been established, and John Sinclair, as professor of modern English language, had insisted that courses on English language should be a compulsory component of this new degree. This necessitated the retraining of teacher trainers, and David—now a teacher trainer—was one of the first to attend lectures on the subject given by John Sinclair and Malcolm Coulthard. In the early 1970s, he studied for a master's degree at the University of Birmingham, and subsequently joined the School of English to act as a research assistant on government funded research projects. He then became a full-time lecturer. It was his work on these projects which became the subject matter of his PhD, and which led to the publication of *Discourse Intonation and Language Teaching* (Brazil, Coulthard, & Johns, 1980).

In his teaching he had the ability to make complex ideas seem simple. He had a way of teaching that made students—and his colleagues—feel that they were participating in a joyful discovery process in which David was learning just as much as they were. He came into academic life later than most scholars, though the advantages of this outweighed the disadvantages. He had a mind untrammelled by preceding practice, and this enabled him to place at the center of his description of intonation those features of speech that other writers felt they had to peripheralize: performance factors and contextual considerations. Other descriptions would only have recourse to such considerations when all the possibilities of ingenious syntactic explanation were exhausted. David, by contrast, placed such considerations at the center of his description. As a result, he produced a model which was at once elegant, simple, and above all, teachable—and his contribution to intonation studies had an immediate impact wherever he lectured. The only disadvantage of his coming late to academic life was that his work did not gain ready acceptance amongst those who were already established scholars in the field.

He retired in 1986, but far from becoming inactive, he undertook a series of secondments and lecture tours overseas. The time he had at his disposal also enabled him to undertake writing projects which culminated in the publication of *Pronunciation for Advanced Learners of English* (Brazil, 1994) and *A Grammar of Speech* (Brazil, 1995). It was only toward the end

of his life that his work began to earn recognition beyond the circle of people who had come into personal contact with him. His work, particularly *The Communicative Value of Intonation in English* (Brazil, 1997), is increasingly cited and borrowed from in pedagogical texts, and his own *Pronunciation for Advanced Learners of English* (Brazil, 1994) brought him gratifyingly large royalties in the year following its publication. His last and most ambitious publication, *A Grammar of Speech*, was published in the early part of 1995. It represents a fundamental rewriting of grammar, based not on the notion of the sentence, but on the notion of a communicative chunk, the “telling increment,” which has syntactic, intonational, and communicative requirements in order to be complete. The goal is to represent a unit of grammar not as a finished entity available for inspection, but as “something that is now-happening, bit by bit, in time, with the language being assembled as the speaker goes along” (Brazil, 1995, p. 37). It is a matter of great regret that David died before he could receive the accolades this publication was awarded—it won the English Speaking Union’s Duke of Edinburgh award for Applied Linguistics in 1995.

All those who knew David would say three things about him: “He is one of the nicest men I have ever met,” “He is a great teacher,” and “He is an original thinker.” He had affability, charm, and an ability to relate to everyone he met. Many people find academics intimidating and condescending: everyone who met David would, however, immediately comment on his approachability, and the friendly way in which he would engage with people in whatever most interested them.

Bredella, Lothar

EVA BURWITZ-MELZER

Lothar Bredella (b. 1936) is one of the most eminent scholars in the field of intercultural learning and the teaching of literature to learners of foreign languages. As a prolific writer and chairperson of a graduate school on the didactics of understanding others his influence extends far beyond Germany.

Bredella started his academic career at Goethe University Frankfurt where he received his PhD in 1968 and was appointed professor of English studies and the teaching of literature in 1972. In 1975 he was offered a chair at Justus-Liebig University Giessen, where he spent the most important years of his professional life until he became a professor emeritus in 2004. Bredella was a visiting professor at the University of Wisconsin, Milwaukee (1985) and at Simon Fraser University Vancouver (1993).

Bredella is a former president of the German Association for American Studies, the German Society for Foreign Language Research (DGFF), and a member of several other professional organizations. His most important academic achievement was the co-foundation of the Giessen graduate school (*Didaktik des Fremdverstehens*) in 1991 with his colleague Herbert Christ, an interdisciplinary postgraduate program dedicated to research in the area of intercultural understanding and learning. This graduate school became the starting point of a large number of academic careers in the field of intercultural learning and is documented in many books, edited or co-edited by Bredella and mostly published in the series *Giessener Beiträge zur Fremdsprachendidaktik* (Gunter Narr). Risager (2007, p. 116) names Bredella as one of the main representatives of a “*rapprochement . . . between culture pedagogy and literature pedagogy*.” The Giessen graduate program

has facilitated broad discussions of the role of literature in language teaching, being not least interested in reading comprehension from a hermeneutic perspective, including such psychological-cognitive skills as empathy, perspective awareness, perspective differentiation, perspective takeover and perspective coordination in connection with the pedagogical work on fictional texts in a foreign language.

Bredella's research interest is in literary theory, especially receptionist literary theory, and its implications for the teaching of literature; the analysis of the process of understanding and the development of teaching methods; and theories of intercultural understanding and the connection between literary and intercultural understanding in foreign language learning. A recent focus of his work is questions of educational philosophy and politics, reflected in statements about German National Educational Standards and their reductionist view of *Bildung* and education in the broadest sense. His latest publications are mainly concerned with the theory of intercultural learning and its manifold implications for the teaching and learning of a foreign language in contrast to transcultural concepts.

Among his most important publications is his *Einführung in die Literaturdidaktik* (1976), which was a “standard classic” in German universities, now replaced by a book co-written with Burwitz-Melzer, *Rezeptionsästhetische Literaturdidaktik* (2004). The central concepts of his approach to the understanding of fictional texts are presented in his monographs *Das Verstehen literarischer Texte* (1980) and *Literarisches und interkulturelles Verstehen* (2002). His most recent publication, *Das Verstehen des Anderen* (2010), embraces all the important

DOI: 10.1002/9781405198431.wbeal0109

features of his oeuvre and develops them into a comprehensive theory of “understanding otherness” through fictional text; it includes ideas from many other disciplines, philosophy, social psychology, and cultural theory. Very influential are the numerous anthologies Bredella edited with colleagues, as for example with Christ (1994), which outlines Bredella’s concepts of intercultural learning, with Delanoy (1999), with Meißner, Nünning, and Rösler (2000), and Delanoy and Surkamp (2004). Some of his articles appeared in English, for example “The Tension between Assimilation and Identity Politics in James Maloney’s Young Adult Novels ‘Douggy’ and ‘Gracey’” (2000a), “Literary Texts” (2000b), and “For a Flexible Model of Intercultural Understanding” (2003).

Broeders, A. P. A.

TESSA VAN CHARLDORP

A. P. A. (Ton) Broeders (b. 1946) has published extensively in the field of forensic phonetics and still contributes greatly to the professionalization of the field of forensic linguistics and forensic science in the Netherlands and abroad. Broeders does this by questioning the value, validity, and reliability of technical and scientific forensic evidence. He is concerned with the way in which scientists—but also lawyers, prosecutors, and judges—formulate conclusions based on forensic research, and stresses the important role they play in the criminal justice process.

Academic and Working Life

Broeders was born in Breda, a town in the south of the Netherlands, where he obtained his secondary school diploma (1964). He received a university degree (cum laude) in English Language and Literature from the University of Nijmegen (1972) and spent the next sixteen years as a lecturer in English Language and Linguistics at the same university. After taking graduate courses in acoustics, audio recording, speaker recognition, and speech technology, as well as having spent some time in the United States as a visiting scholar (at the City University of New York and the University of California at Berkeley, 1986–87), Broeders joined the National Forensic Science Laboratory of the Ministry of Justice in Rijswijk, the Netherlands (1988). Here he was appointed as a forensic phonetician and linguist.

In 1996, Broeders became the head of the Department of Handwriting, Speech and Document Examination at the Netherlands Forensic Institute (NFI). After running this department for five years, he was appointed as chief scientist at the NFI (2002–07).

Since 1992, Broeders has served as a forensic expert on over a hundred court cases in the areas of speaker identification, text analysis, earwitness identification, and intelligibility enhancement of audio recordings. Furthermore, he served as an expert witness for the UN International Criminal Tribunal for the former Yugoslavia in The Hague in 2000 and 2002.

In 2003, Broeders received his PhD from Leiden University. His dissertation, entitled “In Search of the Source: An Exploration of the Basic Principles of Criminalistics and the Evaluation of Forensic Evidence,” was awarded the Prof. A. E. J. Modderman Prize for criminal law dissertations in 2006.

Views on the Field of Forensic Linguistics

In the early stages of his academic career, Broeders was mainly concerned with forensic phonetics such as voice recognition techniques, speaker identification research through earwitnesses, and audio analysis. Broeders (1996) and Broeders and Rietveld (1995) discuss difficulties with earwitness reliability.

Since the late 1990s, Broeders has been mainly concerned with the professionalization of the field of forensic linguistics and forensic science. He advocates expressing conclusions

in forensic identification disciplines within a logical framework rather than in terms of the traditional verbal probability scales that are still used by expert witnesses in courts worldwide (Broeders, 1999). More specifically, he cautions the field against making “logically incorrect” conclusions (Broeders, 2009). He suggests that experts should always work with two hypotheses, namely the (prosecution) hypothesis that the accused is guilty and the (defense) hypothesis that the accused is not guilty (Broeders, 1999). In his inaugural lecture at Leiden University Broeders pointed out that, in their formal training, criminal judges in the Netherlands are not taught how to evaluate scientific evidence. Broeders argues that this subject should be introduced in all criminal law curricula (Broeders, 2005).

Current Interests

During his academic career to date Broeders has served on numerous PhD committees. He was a founder member and former Executive Committee member of the International Association for Forensic Phonetics and Acoustics, and is currently a member of the editorial board of the *International Journal of Speech, Language and the Law* as well as *Expertise en Recht* (Expertise and the Law).

Broeders resides in the Netherlands and divides his time between the University of Leiden and the University of Maastricht, where he holds the chair of criminalistics. Since its opening in 2008, Broeders has been the scientific director of the Maastricht Forensic Institute (TMFI), the second largest forensic institute in the Netherlands.

Broeders’s home Web page can be found at <http://www.maastrichtuniversity.nl/web/Faculteiten/FdR/Thema/OverDeFaculteit/Medewerkers/MedewerkersAbc/BroedersA.P.A..htm>

Brown, Penelope

YOUNHEE KIM

Brown, Penelope (born on November 2, 1944 in Summit, New Jersey, USA) is probably best known for the monograph, *Politeness: Some Universals in Language Usage* (Brown & Levinson, 1987) coauthored with Stephen Levinson. Penelope Brown is currently a senior researcher emerita at the Max Planck Institute for Psycholinguistics in the Netherlands.

She obtained her BA in psychology from Carleton College in Minnesota in 1965 and her MA in anthropology and linguistics from the University of Iowa in 1970. She received a PhD in anthropology from the University of California, Berkeley in 1979 specializing in sociolinguistics, language and thought, and Mesoamerican ethnography.

Brown's early research is influenced by women's studies and her sociolinguistic interest in women's speech combined with her work on politeness. As a linguistic anthropologist, she has done her fieldwork in the Tzeltal Maya community of Tenejapa, in southern Mexico. The data she initially collected in that fieldwork provided the main database for her dissertation "Language, interaction, and sex roles in a Mayan community: a study of politeness and the position of women" as well as providing a conversational database relevant for her later work. In the dissertation, and in a series of publications (e.g., Brown, 1980), she addressed the topic of *women and politeness*. Meanwhile, she coauthored an essay with Stephen Levinson, and published it in 1978, which became the core of their 1987 book *Politeness: Some Universals in Language Usage*. This monograph has come to be accepted as the classic treatment on politeness in communication. In this monograph, Brown and Levinson (1987) develop a rich theory of linguistic politeness around Goffman's concept of *face*. Social interaction is viewed as cooperative activity, in which members work to maintain each other's *face*. This concept of *face* is further divided into two aspects, positive and negative face, or one's positive self-esteem versus one's freedom to act. The universal availability of these two kinds of face wants along with rationality provides the basis for the proposed universal principles of Brown and Levinson's politeness model, which tries to explain the linguistic commonalities of politeness utterances across languages.

Brown joined the Max Planck Institute (MPI) in the mid-1990s and has conducted collaborative comparative research there ever since. Spatial language and cognition has been one of the strongest research strands in the MPI's comparative research project, and in collaboration with her colleague and husband Stephen Levinson, Brown produced extensive research on spatial concepts and language in Tzeltal. In their 1992 paper, Brown and Levinson (1992) report on a linguistic and conceptual gap of "left" and "right" in Tenejapan Tzeltal. They found that Tenejapans use a number of different systems (including a "geocentric" system) to construct a division of space instead of using an "egocentric" system. Levinson and Brown (1994) use the example of Tzeltal to argue that human spatial cognition is not primarily egocentric, presenting a challenge to Kant's view of human conceptions of space and the prevailing assumption among cognitive scientists.

For Brown, research on spatial language and cognition has been a way to explore a bigger research agenda, *the relationship between language, culture, and cognition*, more specifically, the role that linguistic categories play in cognition from a developmental and cross-cultural perspective and the ways in which this role is influenced by the specific

language and culture. Pursuing a comparative perspective, her research contributes to ongoing debates in the field, for example, universalism versus relativism. Based on her Tzeltal data, she has produced evidence that Tzeltal adult spatial language differs radically from languages where spatial relations are encoded in adpositions, for example, “in,” “on,” “under” (e.g., Brown, 1994, 2006b). She has pursued this line of research further in a longitudinal study of child language acquisition in Tzeltal, and has shown that there are culture- and language-specific influences on the children’s acquisition patterns (Brown, 1998a, 2001, 2007a; Brown & Levinson, 2000, 2009).

Brown’s research on child language acquisition not only addresses spatial vocabulary, but also includes acquisition of morphology (Pye, Pfeiler, De León, Brown, & Mateo, 2007), semantics (Brown, 2007a; Narasimhan & Brown, 2009), argument structure (Brown, 2007a, 2008; Bowerman & Brown, 2008), and the role of child–caregiver interaction (Brown, 1998b, 2002a), and Tzeltal children’s development of narrative style (Brown, 2004).

Whether and how languages structure our experience differently has been an important question for Brown. Therefore, crosslinguistic investigation of argument structures and verb semantics, or more broadly, patterns of linguistic encoding of events have been an important research topic for her (Brown, 2007c). Her research on crosslinguistic investigation of argument structure and its influence on language acquisition culminated in the coedited volume with Bowerman, *Crosslinguistic Perspectives on Argument Structure: Implications for Learnability* (Bowerman & Brown, 2008). This volume offers an interdisciplinary perspective on verb argument structure and shows that languages are much more diverse in their argument structure properties than has been recognized, challenging the existing assumption that argument structure is strongly constrained by a set of universal principles. In her chapter of the volume, Brown (2008) investigated the relationship of verb semantics to argument ellipsis. Brown suggests that noun ellipsis in transitive sentences is related to the semantics of the verbs and this ellipsis may be a cue to helping children learn the semantics of verbs. Brown also coedited a special issue of the journal *Linguistics*, “The Linguistic Encoding of Multiple-Participant Events” (2007) with Narasimhan and Eisenbeiss. The special issue sketches the challenges that multiple-participant events pose for linguistic and psycholinguistic theories and demonstrates that there is considerable crosslinguistic and within-language variation in how the participants in multiple-participant events are encoded both at the lexical and the constructional levels (Narasimhan, Eisenbeiss, & Brown, 2007).

As part of a large-scale comparative study at the MPI, Brown also conducted a cross-cultural comparison of interactional patterns, revealing universals and particulars of interactional practices such as turn-taking systems, gaze behavior, person reference, and questioning (Brown, 2007b, 2010; Rossano, Brown, & Levinson, 2009; Stivers, et al., 2009). In her latest work, Brown examines the effect of one interactional practice—pointing for joint attention—on children’s social-cognitive development in two different cultures, the Tzeltal Mayan community and the Rossel islanders of Papua New Guinea (Brown, 2011). She has also written numerous journal articles and encyclopedia entries on key topics of linguistics (e.g., Brown, 2002b; Brown, 2006a).

Brown continues to be a prolific writer and researcher. She is currently writing two books on Tzeltal: one on spatial language and cognition, and the other on conversation. Her work on linguistic pragmatics and on language and cognition provides an invaluable source of insight for students of applied linguistics, particularly those who are interested in the relationship between language learning, culture, and cognition.

Bush, Vannevar and Hypertext

THOMAS COBB

Widely known as the father or even guru of hypertext and its principal medium the World Wide Web, Vannevar Bush (1890–1974) never employed either of these names. Rather, he envisaged a “memex” system for organizing and retrieving multimedia information on microfilm, memex being a word like rolodex or index (card), that is, more redolent of the actual period of his activities. Yet Bush’s memex system went far beyond any index-based information retrieval system and in many ways is the true precursor of the Internet, at least on the concept level.

An engineer, technocrat, and pioneer of analog computing, Bush became part of the mass mobilization of US intellectual resources in World War II. Director of the Office of Scientific Research and Development (1941–7), he was charged with focusing the minds of 6,000 leading US academics and scientists on matters of defense, via, for example, the Manhattan Project that developed the atomic bomb. After the war, Bush became presidential science advisor and hoped to carry the war time mobilization into useful peacetime projects. The basic details of Bush’s work and life are well presented in his Wikipedia entry.

What emerged as interesting for Bush in his war work was the issue of information management. *Information* for Bush was roughly equivalent to *civilization*, with retrieval its principle mechanism. In his words: “[Information retrieval] is a much larger matter than merely the extraction of data for the purposes of scientific research; it involves the entire process by which man profits by his inheritance of acquired knowledge” (Bush, 1945, p. 106). And yet, at about mid-century effective information retrieval was starting to become a problem. Bush’s efforts to mobilize a nation’s intellectual resources had made him aware that there was already in existence more printed and other information available on any given topic than was easily manageable, even as the creation of new information was accelerating. Shortly after the war, in an early and prescient encoding of the sense of being information ridden, Bush described the present state of info-civilization:

Science has provided the swiftest communication between individuals; it has provided a record of ideas and has enabled man to manipulate and to make extracts from that record so that knowledge evolves and endures throughout the life of a race rather than that of an individual. . . . There is a growing mountain of research. But there is increased evidence that we are being bogged down today as specialization extends. The investigator is staggered by the findings and conclusions of thousands of other workers—conclusions which he cannot find time to grasp, much less to remember, as they appear. (p. 101)

(Lengthy citations will help establish the prescient yet at the same time dated and even quaintly optimistic quality of Bush’s thinking as viewed from the present. This citation is from the main document for which Bush is still known, an article written just after the war entitled “As We May Think” and published in *The Atlantic Monthly* in July, 1945.)

Bush’s problem with information was not really that there was getting to be too much of it (he seemed never to question the engineer’s maxim that more information is usually better), but that the means available for handling it had not kept pace of the means of producing it:

2 BUSH, VANNESVAR AND HYPERTEXT

The difficulty seems to be, not so much that we publish unduly in view of the extent and variety of present day interests, but rather that publication has been extended far beyond our present ability to make real use of the record. The summation of human experience is being expanded at a prodigious rate, and the means we use for threading through the consequent maze to the momentarily important item is the same as was used in the days of square-rigged ships. (Bush, 1945, p. 102)

The square-rigged ship in question was basically the alphanumeric, name-based hierarchical index system, like the names-within-names of the folder system on the hard drive of your computer:

The real heart of the matter of selection . . . goes deeper than a lag in the adoption of mechanisms by libraries, or a lack of development of devices for their use. Our ineptitude in getting at the record is largely caused by the artificiality of systems of indexing. When data of any sort are placed in storage, they are filed alphabetically or numerically, and information is found (when it is) by tracing it down from subclass to subclass. It can be in only one place, unless duplicates are used; one has to have rules as to which path will locate it, and the rules are cumbersome. Having found one item, moreover, one has to emerge from the system and re-enter on a new path. (p. 107)

The solution to this problem is to organize information more as humans do, or “as we may think,” that is, in associative leaps and links:

The human mind does not work that way. It operates by association. With one item in its grasp, it snaps instantly to the next that is suggested by the association of thoughts, in accordance with some intricate web of trails carried by the cells of the brain. (p. 107)

This scheme, however, is as we “may” think since we do not yet have all the details:

Man cannot hope fully to duplicate this mental process artificially, but he certainly ought to be able to learn from it. In minor ways he may even improve, for his records have relative permanency. The first idea, however, to be drawn from the analogy concerns selection. Selection by association, rather than indexing, may yet be mechanized. One cannot hope thus to equal the speed and flexibility with which the mind follows an associative trail, but it should be possible to beat the mind decisively in regard to the permanence and clarity of the items resurrected from storage. (p. 107)

The plan probably seemed idle futurism at the time, but Bush envisaged a real device, which he named a memex (short for memory extender), a “device in which an individual stores all his books, records, and communications, and which is mechanized so that it may be consulted with exceeding speed and flexibility” (p. 107). Physically, the memex would resemble a desk, the top of which would bear “slanting translucent screens on which material can be projected for convenient reading,” as queried from a “keyboard, and sets of buttons and levers.” Space for all this information is no problem: “The matter of bulk is well taken care of by improved microfilm. . . . if the user inserted 5,000 pages of material a day it would take him hundreds of years to fill the repository, so he can be profligate and enter material freely” (p. 107). The information to be thus collected would not be limited to a text format:

Most of the memex contents are purchased on microfilm ready for insertion. Books of all sorts, pictures, current periodicals, newspapers, are thus obtained and dropped into place. Business correspondence takes the same path. And there is provision for direct entry.

On the top of the memex is a transparent platen. On this are placed longhand notes, photographs, memoranda, all sorts of things. When one is in place, the depression of a lever causes it to be photographed onto the next blank space in a section of the memex film, dry photography being employed. (p. 7)

As enthusiastic as Bush was for the simple collecting of information that a memex would make possible, it was more the accessibility of particular pieces of information that interested him, and following that their linking into useful associations. For this he envisaged making full use of traditional indexing:

There is, of course, provision for consultation of the record by the usual scheme of indexing. If the user wishes to consult a certain book, he taps its code on the keyboard, and the title page of the book promptly appears before him, projected onto one of his viewing positions. Frequently used codes are mnemonic, so that he seldom consults his code book; but when he does, a single tap of a key projects it for his use.

(Like hyperlinks?) But more than index links, it is the associative links that Bush is really interested in:

All this is conventional, except for the projection forward of present-day mechanisms and gadgetry. It affords an immediate step, however, to associative indexing, the basic idea of which is a provision whereby any item may be caused at will to select immediately and automatically another. This is the essential feature of the memex. The process of tying two items together is the important thing. (pp. 107–8)

More specifically:

When the user is building a trail, he names it, inserts the name in his code book, and taps it out on his keyboard. Before him are the two items to be joined, projected onto adjacent viewing positions. . . . Thereafter, at any time, when one of these items is in view, the other can be instantly recalled merely by tapping a button below the corresponding code space. Moreover, when numerous items have been thus joined together to form a trail, they can be reviewed in turn, rapidly or slowly, by deflecting a lever like that used for turning the pages of a book. It is exactly as though the physical items had been gathered together to form a new book. (p. 108)

Minus the buttons, levers, microfilm, and dry photography, and with slanting screens replaced by virtual windows on a single but still slanting screen, functionally Bush's memex pretty much describes the laptop your writer is working on right now. But one big difference is that the latter can access not only all the information on a single hard disk but also that on the many other hard disks and stored in networks that "over a billion people have access to [in] the most extensive expansion of information ever compiled" (Wolf, 2007, p. 221).

Hits and Misses

Most of the quarter million hits for "Vannevar Bush" currently itemized on Google, at least on the first few pages, emphasize the amazing accuracy of Bush's predictions, but in fact his track record is mixed. Take the notion of a named information trail, Bush's key idea about how we may think. Technically, this has turned out even better than Bush predicted: the trail of this research for this very entry, that is, the pages that this author

actually went to from the search engine's offering the day before, is automatically stored in chronological order on the browser and accessible in the Internet Explorer's "Favorites" under "History: Yesterday" (and similarly in other browsers). Here, the false starts, dead links, and ads that a typical search now entails can be edited out, something Bush almost certainly did not envisage. But more importantly, somehow the idea of a trail of stored associations has not been the hit that Bush predicted. This author rarely uses his browser's History feature in Web searches, preferring to save good finds as a list of links or documents, either way losing the sequential character of a trail or other information about what he may have been thinking. This is actually quite common: a Google search on "IE favorites history" leads mainly to articles from Microsoft and others about how to use the feature, and there are no studies of how or whether it gets used by information workers (in, for example, the open access database of *Educational Technology Research & Development* at www.springerlink.com/content/1042-1629/).

Other key ideas have fared better. The notion of a mechanized associative search began as pure fantasy but step by step became clear and operable. The notion of capturing an association once provided by a search engine is clear enough, but how the search engine provides the raw material for associations was less so without the replacement of microfilm by digital media and then the many subsequent upgrades of digital processing power. This power was not long coming, and Bush's basic idea of an associative, non-hierarchical search was soon realizable in prototype. An early realization from IBM was Luhn's (1957) proposal to leave the to-be-searched archive itself largely unstructured (like the Web of today) and then retrieve information from it by "using words as indexing units for documents and measuring word overlap as a criterion for retrieval" (p. 316). This is a type of full text search, rather than a folder name and filename (index) search, such as we have enjoyed on our PCs since roughly 2005. The basic idea was developed and tested over the 1970s and 1980s, and particularly since 1992 through the ongoing Text Retrieval Conference series (TREC, sponsored by National Institute of Standards and Technology, which regularly cites Bush's ideas in its proceedings).

The search algorithms now deployed by Google and others are too complex to discuss in the present forum except to say that there is continuity between the associative principle of Bush and the modern search engine of Google and others. Bush is regularly cited as an inspiration by Googleplex fellows including Singhal (2001). Some recent search refinements Bush did not anticipate but that will resonate for applied linguists are that search words are stemmed (fleshed out as families), and multiword searches are recast as phrase first (thus *White House* is searched as a whole phrase first, then conjunctively, and only finally disjunctively). But these refinements are all continuous with Bush's basic concept, and indeed Bush is in some ways still ahead of Google in that a Google search remains a word-form dominated keyword search, with all the limitations pertaining thereto, where, for instance, money *bank* may be sought but river *bank* found. The final realization of Bush's associative idea awaits the fuller implementation of the "semantic Web," apparently just around the corner, where searches will proceed on a conceptual level through XML-encoded documents (Antoniou & Van Harmelen, 2004).

To summarize, Vannevar Bush came up with a remarkably specific blueprint for not only where we have got to in the universe of digital media but also where we may yet be going. It is thus ironic that at the moment of realization the question is increasingly posed, Is this where we want to be going?

What Bush Did Not Predict

We are presently seeing the simultaneous triumph of Bush's ideas along with the emergence of worries that a fully linked docuverse may just be another type of information overload

that this time there really is no solution for. A whole semi-popular subgenre of worrisome assessments has recently sprung up to argue points like “The Internet is rotting your brain” (Miller, 2010) and “Google is making us stupid” (Carr, 2008). Nicholas Carr’s *The Shallows* (2010) is a non-academic but still serious work expressing a growing unease about the kinds of mental experience that a fully linked docuverse leaves us with. The basic problem is that fully linked documents provide mainly distraction and overload, and far more of it than people can actually cope with, particularly in the case of those who have had little other experience with texts and information such as children.

This piece from *The Shallows* looks like a realization of Vannevar Bush’s happy daydream of buttons and levers:

For more than a decade now, I’ve been spending a lot of time online, searching and surfing and sometimes adding to the great databases of the Internet. The Web has been a godsend to me as a writer. Research that once required days in the stacks or periodical rooms of libraries can now be done in minutes. A few Google searches, some quick clicks on hyperlinks, and I’ve got the telltale fact or pithy quote I was after. Even when I’m not working, I’m as likely as not to be foraging in the Web’s info-thickets, reading and writing e-mails, scanning headlines and blog posts, watching videos and listening to podcasts, or just tripping from link to link to link. (Carr, 2010)

The difference, however, is that Carr here is building up to an ultimately negative assessment of this experience, where all this quick, targeted, or scanning type of linked, associative, and highly distractible “reading” is leaving him and presumably others less and less inclined, or possibly able, to get to the end of a longer texts with complex arguments.

Carr’s evidence is mainly anecdotal, but he may have a point. Research studies both broad and narrow are starting to look at the costs and benefits of hypertextual, lateral, or search-based reading (to name just a few of the terms competing to name the phenomenon). An broad look is the five-year study (by Rowlands & Nicholas, 2008) of the computer logs from two heavily used research UK Web sites, showing that link-enabled researchers both young and old tend to skim rather than read, hop from one source to another, rarely return to any source they have already read, and rarely read more than two pages of any document, thus not so much reading as “power browsing horizontally” through abstracts and content pages in search of quick references for school assignments and academic tasks.

From the perspective of process and detail, reading researchers DeStefano and LeFevre (2007) review 38 experimental studies on the cognitive consequences of hypertext reading “in order to test the hypothesis that activities specific to hypertext can increase cognitive load and impair learning.” (p. 1617). The researchers wonder whether, “When people follow links, they may lose track of where they are in the text, of their reading goals, of the larger context for the node, or of material activated in working memory” (p. 1627). Their review concludes that generally in the experiments reviewed, “many features of hypertext resulted in increased cognitive load and thus may have required working memory capacity that exceeded readers’ capabilities” (p. 1636), or at least some readers’ capabilities, since “the various manipulations [entailed in linked or hypertext reading] were often most detrimental to the reading processes of less-knowledgeable readers and for readers with low working memory capacity” compared to traditional linear presentations of text.

Few armchair ideas ever get realized, fewer still without surprises. Vannevar Bush formulated his vision of creating and reading linked texts from the perspective of a long-standing offline or linear reader. He almost certainly never thought about what kind of reading would take place once readers were “digital natives,” virtually raised on associatively linked or hypertextual reading. The idea is now emerging that coping with multiple interlinked texts constitutes something of a new literacy, which like the old linear model

will have to be the subject of deliberate training and extensive practice, possibly involving either new cognitive skills, or a type of bi-modality between two literacies (see Ong, 1982, p. 175, for speech and text; and Wolf, 2007, chap. 9, for text and hypertext), or both. It is often said that learning to talk is free while learning to read is expensive, creating winners and losers (Gough & Hillinger, 1980; deHaene, 2009); it will probably turn out that learning to read hypertexts while beneficial to the able will be even more expensive, like reading but more so. At the moment, children appear to be floundering in the new literacy while their teachers persist with training and testing in the old—yet another digital divide.

Butters, Ronald R.

JAN CHOVANEC

Ronald R. Butters was born in 1940 in Cedar Rapids, Iowa, USA. He obtained his BA and PhD degrees in English at the University of Iowa. Immediately after graduation, he took up a position at Duke University, where he taught for 40 years until his retirement in 2007. He was Professor of English (1990) and Professor of Cultural Anthropology (2000) at Duke University, and is now Professor Emeritus. From the 1970s, he was Chair of Duke University's linguistics program and from 2008 President of the International Association of Forensic Linguistics. He is currently a coeditor of *The International Journal of Speech, Language, and the Law*, and was formerly an editor and editorial board member of various journals, including *American Speech*, *Papers in Linguistics*, and *Journal of Metaphor and Symbolic Activity*. His book *Displacing Homophobia* (1989), coedited with John Clum and Michael Moon, won the 1989 Conference of Editors of Learned Journals Best Special Issue award.

Throughout his professional career, Professor Butters has worked primarily in the field of sociolinguistics, where he is best known for his studies in current American English. More recently, he has embraced legal linguistics and the new discipline of forensic linguistics, with a focus especially on trademarks, contracts, and statutes. Since the 1980s, he has prepared over 300 reports and provided expert linguistic testimony in over 60 depositions and court cases.

His sociolinguistic studies in American English have focused on dialectological research and language variation and change, as well as on nonstandard lexical and grammatical forms, especially in Black English and in dialects spoken in the Southern states. He has been most influenced by Leonard Bloomfield, Noam Chomsky, William Labov, Roger Shuy, Raven McDavid, and his colleague, the sociolinguist Walt Wolfram. Butters has conducted research on such issues as the pronoun *y'all* (noting the changes in the pronoun paradigm in the South), word order, and multiple modals in the Southern states. Like all of his influencers except Chomsky, he is interested in the links between language and the relevant speech community. In his view, however, Chomsky's emphasis on rigorous linguistic theory and the early "transformationalist" concentration on the psychology of language highlighted the need for sociolinguistics which had only been nascent in the work of Bloomfield and McDavid.

In his major sociolinguistic work (1989), Butters critically tackles the divergence hypothesis, which claims that Black and White English vernaculars are becoming more different from each other. Numerous linguistic variables (most crucially the invariant *be*, vowel fronting, and verbal *-s*) are shown not to be evidence of actual divergence. On the contrary, there are features (such as final consonant cluster simplification, /l/ vocalization, and embedded yes/no questions) that either indicate convergence or, at least, provide counterarguments to divergence. In this controversy, Butters adopts the position that there is "a mild sort of stable convergence in which linguistic changes arise in both the White and Black communities. The communities borrow from each other, but the dominant pattern of convergence is towards the culture of the majority" (1989, p. 180).

His sociolinguistic approach is also present in his research as a forensic linguistics scholar. Beginning in the 1980s, law firms began increasingly to seek Butters's advice as an expert witness in legal cases. His research interests have now turned to linguistics and

the law, including the interpretation of the language of contracts and statutes, allegations of defamation, the verifiability of confessions and interrogations, and the interpretation of spoken, written, and electronic linguistic evidence—all areas in which he also offers legal consultancy.

In his early studies on statutory interpretation, Butters applied sociolinguistic methodology: He sought to establish the meaning of a term within a particular discourse community by examining the contexts in which the term is used. As an expert witness in cases involving statutory interpretation, he proceeded to triangulate the meaning (e.g., of the term “committed for pecuniary gain,” see Butters 1993) on the basis of: (a) numerous court rulings (which provide meanings sanctioned by the discourse community), (b) the authorial/legislative intent as represented in the legislative proceedings, and (c) the ordinary language definitions and understandings/uses of a given term.

The expert linguistic evidence given by Butters in various cases has provided the basis for many of his articles in which he discusses real-language data against relevant theoretical approaches. Thus he has offered a semantic, pragmatic, and semiotic interpretation of instructions on scratchcard lottery tickets (2004), explored sociolinguistic variation in the courtroom (2007a), and explained ambiguity in legislative instruments (1993). He has also been involved in several major criminal cases. In *State of Louisiana v. Wilbert Rideau* (2005), he revealed linguistic inconsistencies in the defendant’s confession, pointing out also that significant portions of the crime’s witness statements were tainted by the hand of the interviewing police. In *State of Florida v. Michael Gordon Reynolds* (2008), he analyzed an error in the trial transcript which led to a significant ambiguity in a DNA expert’s testimony—an ambiguity that could have unduly influenced the jury to sentence the defendant to death.

However, the major focus of his more recent work in forensic linguistics is trademark litigation (see, e.g., Butters 2007b, 2008a, 2008b; Butters & Westerhaus, 2004). In this area, Butters has been especially interested in the distinction between trademarks and generic terms, focusing on the interface between the lexical conception of such terms as common nouns and the legal understanding of their genericness. In assessing the difference, he draws on dictionaries, inductive analysis of historical and contemporary print-material records, and occasionally native-speaker introspection as represented in sociolinguistic surveys, in order to establish the extent to which the public is familiar with a trademark—what they know and what they believe. From a diachronic perspective, as Butters observes, trademarks may undergo genericide, that is, lose their association with a particular producer and become generic (e.g., *aspirin*, *thermos*). Generic words then identify the product rather than a particular brand of the product. The move toward genericness occurs when trademarks (which in legal conception must be used solely as “adjectives,” i.e., nouns used attributively, as in *Xerox photocopy*) are either: (a) used as nonappositive independent nouns (often inflected and with the plural suffix), (b) converted into verbs, (c) printed in lower case, or (d) used in figurative senses. The exact position of the boundary between a trademark and a generic word is fuzzy and often subject to debate.

As manufacturers, in their attempts to prevent their trademarks from becoming generic, continually try to increase public awareness of their trademarks, the process of genericide has become, Butters argues, quite rare in the last few decades. It has been replaced by what he calls “pseudogenerics,” that is, trademarks which often exhibit features of genericness, though the public still recognizes them as brand names (e.g., *Xerox*, *Kleenex*, *Google*).

As a forensic linguist, Butters has explored the following language-related issues of trademark litigation: the likelihood of confusion (of two or more marks), the strength of the mark (on the scale of generic/descriptive/suggestive/fanciful/arbitrary), and the propriety of the mark (whether it is “scandalous” or “disparaging”). He has supplemented

these three traditional dimensions with a fourth aspect amenable to expert linguistic consultation in trademark cases, namely “trademark dilution” (see Butters, 2008b), which is legally defined as the “lessening of the capacity of a famous mark to identify and distinguish.”

Some of the most notable cases of trademark litigation in which he has testified include: *Aventis Pharmaceuticals v. Advancis* (2004), where he confirmed the possible linguistic confusion between Advancis and Aventis; *Steak N Shake v. Burger King* (2004), where, on the basis of historical research, he found the term “steakburger” to be generic; *Hilliard Enterprises v. Warren Oil* (2003), where he used semiotic analysis when assessing the use of a checkerboard symbol; and the famous landmark trademark case of *Harjo et al. v. Pro-Football* (1997), which concerned the “political correctness” of the trademark “Redskins” for a famous American professional football team. In *Auto-Nation, inc. v. Acme Commercial Corporation et al. d/b/a CarMax the Auto Superstore*, which concerned the possible confusion between the trademarks Auto-Nation and Auto-Mation, the opposing linguist was Butters’s mentor Roger Shuy, who wrote in his book on trademarks that in the end he felt that Butters had the stronger case (Shuy, 2002, p. 143).

Professor Butters is currently working on a monograph on trademarks as linguistic objects. His personal Web page is at <http://trademarklinguistics.com/>.

Byram, Michael

PETER DOYÉ

Michael Byram is an influential theorist of foreign-language education and intercultural education whose thinking has helped to shape policies for and research on pedagogic curricula and the practice of teaching-and-learning of languages all over Europe.

Convinced of the necessity to embed foreign-language instruction in the comprehensive context of general education and to view its task as a contribution to the development of intercultural competence, he concentrates his research on the problems of such an integrative approach and of a joint promotion of language-and-culture learning in particular.

He regards the limitation of foreign-language teaching to the promotion of practical, economically desirable skills as a serious mistake and sees the language-learning process as a holistic development consisting of at least three components: the cognitive, the pragmatic, and the attitudinal. As any other valid educational undertaking, foreign-language teaching comprises the promotion of practical skills, knowledge, and attitudes. Based on work with Zarate (Byram & Zarate, 1997), Byram coined the terms

- *savoirs*: the knowledge of cultures and cultural processes,
- *savoir-faire*: the ability to use this knowledge for the performance of speech acts,
- *savoir-être*: the attitudes of openmindedness and tolerance as a basis for such a performance,
- *savoir-apprendre*: ability to discover other people's cultures and languages, and
- *savoir-s'engager*: critical awareness and evaluation of one's own and other cultures.

These expressions have become a core element in the terminology of any scientific discourse on language education in Europe.

Since 2000, Michael Byram has gone one step further. He has examined the relationship of language education and political education and emphasized the congruence of both in the cognitive, pragmatic, and attitudinal domains (Alred, Byram, & Fleming, 2006). He has proposed a superordinate aim, called "intercultural citizenship," by which he means the willingness to become engaged in political action across linguistic and cultural boundaries and the skills and knowledge needed for this engagement. Byram is convinced that this trinity represents the essential task of political and language education in any civil society of our present globalized world and demonstrates—in his later publications—how it can be practiced (Feng, Byram, & Fleming, 2009).

After an initial period of research and a PhD on Danish literature, Michael Byram's professional career began in the 1970s, when he taught French and German in an English community school to both children and adults. In 1980 he became lecturer in education at the University of Durham, was promoted to senior lecturer in 1989 and reader in 1990. In 1994 he was appointed professor of education at the same university, a position from which he retired as emeritus in 2008. During all these years he trained hundreds of teachers for work in secondary schools in Great Britain and supervised over 70 PhD students in various fields of research. Another important part of his occupation was his work as a consultant of the Council of Europe to the Language Education Policy Profiles of individual European countries, such as Belgium, Finland, Hungary, Norway, and Poland, and

his engagement in the evaluation of a number of bicultural/intercultural European projects. Most fruitful was also his work as special advisor to the Council of Europe Language Policy Division, from which arose the Guide for the Development of Language Education Policies in Europe (Béacco & Byram, 2007). This document, which he wrote together with Jean-Claude Béacco, has become most influential as a basis on which a number of national governments have built their pedagogic curricula and language-teaching programs. Byram has held several visiting professorships including research fellow at the National Foreign Language Center, Washington DC, and visiting professor at Gakugei University, Tokyo.

Michael Byram has published 33 books and numerous articles on foreign-language instruction, on study abroad and on political and general education (Byram 1989, 2008). All these publications are centered around his idea of the role of language teaching and learning in the education of the individual and the development of society. Of course, they always treat different aspects of this concept. The topics range from cultural studies via bilingual and plurilingual education and social identity versus national identity to European citizenship. Some of Byram's books and articles present the procedures and results of his empirical studies, such as his own and joint research projects on language teaching and young people's perception of other cultures, on language learners as ethnographers (Byram, 2001), learning language-and-culture through exchanges, and the representation of target cultures in textbooks for language learning (Byram 1993). He is the editor of the *Routledge Encyclopedia of Language Teaching and Learning* (Byram 2000).

About half his books were published as joint products: He cooperated with a number of influential educationists in Great Britain, France, Germany, and other countries and served as the coeditor, joint author/editor, and contributor of these publications. His books have been translated into other languages, such as French, Italian, Chinese, and Japanese.

Byram's contribution to the promotion of language education certainly lies on the theoretical side. But his practical engagement in various pedagogic projects has also exercised an important influence on the consolidation of existing good practice and the innovation of teaching in conventional contexts. His open and empathetic personality always makes him a welcome speaker at conferences and workshops and a helpful advisor to many a European project. All these activities are accompanied by his membership of various academic societies, such as the Deutsche Gesellschaft für Fremdsprachenforschung and the British Association of Applied Linguistics.

Byram is also a member of the editorial committees and advisory boards of several educational and linguistic journals. He is an elected member of the British Academy of Social Sciences, and he was appointed Chevalier dans l'Ordre des Palmes Académiques in 1995.

Byrnes, Heidi

LOURDES ORTEGA

Heidi Byrnes (1944–) is among the most distinguished foreign language education scholars in the USA. Over more than three decades, her contributions have been characterized by a deeply intellectual commitment to investigating the nature of linguistic competencies that develop through foreign language instruction, and by her leadership in educational innovation and professionalism, where she is well known for having integrated research, praxis, and policy in an exemplary fashion.

Born in Germany, Byrnes visited the USA as a teenager under the auspices of the American Field Service high school exchange program and returned in 1964 to complete a Bachelor of Science in Education from the University of Kansas, followed by a Master of Arts in Modern Languages/Linguistics from Kansas State University. After several years of teaching German and English in Kansas and in her native Germany, she settled permanently in the USA and undertook her doctorate at Georgetown University. There she earned a doctoral degree in German/Linguistics in 1979 and immediately joined the regular faculty of the German Department. She has remained at Georgetown since then, earning the title of full professor in 1991 and of George M. Roth Distinguished Professor of German in 2005.

Byrnes's scholarly contributions are rich and have coherently evolved over the years in synchrony with major disciplinary shifts. In turn, she has encouraged, through the wedding of research and practice, unprecedented innovation in the field of foreign language education and has made unique theoretical contributions to the fields of language testing and second language acquisition.

During the 1980s, Byrnes participated in the theoretical developments that catapulted communicative language teaching to the center of professional international interest, and she played an active role in concomitant communication-oriented assessments. She was particularly instrumental in the development of the American Council on the Teaching of Foreign Languages (ACTFL) proficiency guidelines and oral proficiency interview assessments, including rater training and validation research (Byrnes & Canale, 1986; Byrnes, 1987; Buck, Byrnes, & Thompson, 1989). This and other early work foreshadowed one direction which Byrnes would pursue later, as it demonstrated a keen interest in investigating the relations between assessment and pedagogy, on the one hand, and, on the other, listening, reading, and writing as skills in which texts play a central role (Byrnes, 1984a, 1984c; Swaffar, Arens, & Byrnes, 1991) and in which grammar interacts with discourse in the service of making meaning (Byrnes, 1984b). Much of these efforts also gradually involved encouraging the critical search by the collective of US foreign language educators for theoretical underpinnings for their practice, and the deepening of ties between the foreign language research community and the community of applied linguistics. Two important edited collections in the 1990s (Byrnes, 1992, and 1998) are a good reflection of these two goals.

A related emerging theme in Byrnes's writings at the close of the 1990s was developing a well-justified intellectual and theoretical rationale for the purposes and goals of foreign language education in society and in academia (Byrnes, 1990). These developments in her thinking were profoundly impacted by formative service experiences at Georgetown

University during those years, as department chair for six years and particularly in her work as Associate Vice President for Academic Affairs from 1993 to 1995. The role of administrator in the institutional upper echelons made her realize the importance of programmatic and policy-oriented, broad thinking in justifying the purpose of foreign language studies in the USA. Soon she embarked on a long series of strategic writings which explored how the community of US foreign language educators should function by having university departments think collectively and programmatically (Byrnes & Kord, 2001; Byrnes & Maxim, 2004), by meaningfully mentoring graduate students (Byrnes, 2001), and by resolving the traditional divide between language and content and softening the institutional borders between scholarly and service teaching (Byrnes, 2002a).

Continuing into the 2000s, Byrnes furthered her personal vision of a needed, fruitful overhaul in foreign language education scholarship and professional practice on three fronts: the action-oriented, theoretical, and empirical. First, in 1997 she acted upon long-percolating intellectual insights by spearheading an unprecedented curriculum innovation initiative that spanned all proficiency levels and programmatic components (from materials to teacher training to testing and evaluation), in the Georgetown German Department. This effort resulted in the creation of a successful and comprehensive curriculum for German foreign language education that embodied the careful articulation of content and language learning throughout, in the process doing away with the dividing lines between lower-division and upper-division teaching that she argued plagues most language departments in the USA. This exemplary initiative was developed, implemented, evaluated, and made sustainable in the long term partly thanks to Byrnes's formidable leadership and the unconditional support it garnered from close colleagues, students, and collaborators, many of whom soon became coauthors in key publications about the project; and partly due to sufficient levels of intramural funding as well as funding from the Spencer Foundation. Byrnes also worked along a second, theoretical front by making her curricular ideas transcend beyond her local context and fleshing out the theoretical underpinnings of the main elements of the new curriculum content (Byrnes, 2005) and tasks (Byrnes, 2002b). Importantly, Byrnes imbued both with the constructs of genre and textuality (Byrnes, Crane, Maxim, & Sprang, 2006) under the guidance of systemic-functional linguistic theory (Byrnes, 2006b). It is this novel blend that Byrnes advocates as an optimal solution for securing the future of foreign language education in transnational societies and achieving the mission to support the attainment of advanced levels of language and literacy in additional language learning (Byrnes, 2012). In a third, empirical front, Byrnes and associates have published a number of comprehensive studies that offer evidence regarding the linguistic and literacy competencies (Byrnes, Maxim, & Norris, 2010) and the curricular and educational learning outcomes (Pfeiffer & Byrnes, 2009) that ensue from this innovative curriculum. With this empirical work she has come full circle and contributed to the development of new knowledge in the fields of second language testing (Byrnes, 2002b), second language acquisition (e.g., Ortega & Byrnes, 2008; Byrnes, 2009), and, more recently, second language writing (Byrnes, 2011; Byrnes & Manchón, 2012).

Since the mid-2000s, all of Byrnes's work has been strongly influenced by the ideas of systemic-functional linguistics, which in her mind hold the potential to renew curriculum, pedagogy, and applied linguistic theory alike (Byrnes, 2006a). Indeed, Byrnes has found a most profitable match to her long-standing interests of the 1980s and 1990s in this theoretical framework, which addresses language description, use, and learning as a socially grounded phenomenon, always working at the level of oral and written texts that are embedded in social contexts.

Byrnes's service to the profession has also been rich and deep. She has reviewed for numerous international and national funding agencies, publishers, and journals. Particularly central has been her association with the *Modern Language Journal* as a member of the

editorial board uninterruptedly since 1992, an associate editor from 2001 until 2013, and prospective editor-in-chief after 2013. Noteworthy is her conceptualization as associate editor of the highly original biannual *Perspectives* section, which addressed topics of current and controversial professional interest during the first decade of the 21st century. Byrnes has also conducted external reviews of over 25 programs of foreign languages in universities across the USA and other countries, and she has served as evaluator for professional curricula such as those in the Department of Modern Languages of the US Naval Academy and the CIA Language Schools. She was 2011 President of the American Association for Applied Linguistics and has played many other key leadership roles in the American Association for Teachers of German, the American Council on the Teaching of Foreign Languages, the Modern Language Association, the Northeast Conference, and the College Board. In addition, her experiences have lent her a particularly acute sensitivity for professional advocacy in the realm of national language education policy. In 2007, she planned and executed an unprecedented series of panels about these issues at four main conferences in the USA, culminating in an invitational conference and a multivocal exploration of policy needs published in the *Perspectives* section of the *Modern Language Journal* (Byrnes, 2008). Not to be missed is the fact that Byrnes continues to teach unflinchingly in the Georgetown German Department at both the undergraduate and graduate levels and at all curricular levels of language proficiency.

Byrnes's achievements have been recognized internationally with innumerable invitations as keynote and plenary speaker, and she has received many scholarly distinctions. A sample includes a Mellon Fellowship in 1991; the Award for Distinguished Service in the Profession by the Association of Departments of Foreign Languages in 2002; and the ACTFL Nelson Brooks Award for works and writings that have changed the foreign language profession in 2004. Byrnes has also been an Honorary Member of the American Association of Teachers of German since 2008 and an approved Fulbright Specialist in applied linguistics at the Council for International Exchange of Scholars since 2009.

Byrnes continues to inspire new researchers with her innovative thinking and generous intellect. Her integration of intellectual-theoretical, curricular-programmatic, and policy-level interests into a life opus of writings and actions provides future applied linguists with a strong role model for scholarship and professional citizenry.

Canada's Office of the Commissioner of Official Languages

SYLVIE A. LAMOUREUX

The Office of the Commissioner of Official Languages is an important element to Canada's national language policy implementation and development (available online at http://www.ocol-clo.gc.ca/html/index_e.php). In 1963, when tensions between French and English Canada challenged the very future of its Federation (1867), the federal government launched the Royal Commission on Bilingualism and Biculturalism to investigate the realities of bilingualism in Canada and make recommendations to strengthen the confederation based on the principles of two equal founding peoples, the English and the French. The Office of the Commissioner of Official Languages was created in 1969 as part of the first *Official Languages Act* adopted by the Canadian Parliament, based on the recommendations of the Royal Commission on Bilingualism and Biculturalism. The Office of the Commissioner of Official Languages provides policy makers with a mechanism to oversee the implementation of and compliance with a far-reaching language policy meant to bridge two divided linguistics groups, the Anglophones and the Francophones, and their respective minorities.

The scope of the *Official Languages Act* and the authority of the Office of the Commissioner of Official Languages are limited to areas of federal jurisdiction. They do not have jurisdiction in provincial, municipal or private sectors, except privatized former Crown Corporations such as Air Canada and Via Rail.

The role of the Office of the Commissioner of Official Languages is complex and continues to evolve in its complexity. Dyane Adam (2004), Canada's fifth commissioner, explains that the commissioner and its office are neither a language police, nor a simple institutional mediator. As spokesperson for the Office of the Commissioner of Official Languages, the commissioner reports directly to parliament through annual and other reports, as per Sections 66 and 67 of the *Official Languages Act*. The commissioner, an officer of parliament and an agent of change, is appointed for a seven-year renewable term by resolution from the Senate and House of Commons. Graham Fraser, appointed in 2005, is Canada's sixth Commissioner of Official Languages.

A second *Official Languages Act* was adopted in 1988 (<http://laws.justice.gc.ca/eng/O-3.01/FullText.html>) to align the original Act with the *Canadian Charter of Rights* (1982) and amended in 2005 (Office of the Commissioner of Official Languages, 2009). Of note, are the 2005 amendments to Part VII of the *Official Languages Act* that "imposed an explicit obligation on the federal government to take positive measures for the growth and development of official language communities, and to promote the use of both languages" (Fraser, 2009, p. IX).

The duties and functions of the Office of the Commissioner of Official Languages are stated in Part IX of the *Official Languages Act*. Article 56 deals with its mission and mandate. The roles of Office of the Commissioner of Official Languages are many, allowing a diversity of measures and interventions to ensure that the objectives of the *Official Languages Act* are met. The fifth commissioner, Dyane Adam, conceptualized her function as that of institutional mediator that must both regulate and enable conciliation (Adam, 2004, p. 52). Whereas she had identified three distinct roles for her duties as commissioner, that of

ombudsman, auditor, and promoter, the Office of the Commissioner of Official Languages' website now identifies six roles. Along with the three identified by Adam, there are additional roles as liaison, proactive monitor, and court interventions. The original role of promotion has been expanded to include education.

The mission and roles of the Office of the Commissioner of Official Languages allow for investigation through audits, evaluations, research, and studies; recommendations to ensure better compliance with the *Official Languages Act*; receiving of complaints; interventions in and appeal to Federal Courts; and proactive implementation of the Act through monitoring. They also issue report cards following audits of specific departments and follow-up on the implementation of recommendations. This office does not, however, have the power to impose disciplinary sanctions or penalties; they are not, as Adam (2004) confirms, a language police.

The Office of the Commissioner of Official Languages makes an important contribution to knowledge mobilization about bilingualism, official language minorities, and implementation of language policy and planning through its own research activities and those that it supports, including conferences and meetings. These activities and strategies are positive measures for the vitality and promotion of official language communities.

Although the Office of the Commissioner of Official Languages' jurisdiction does not extend to provincial, municipal, or private sectors, Adam (2004) confirms that the commissioners who preceded her did in fact express themselves on matters beyond their jurisdiction. She looks to the scope of Article 82 to find support for their "activism," in their role as ombudsman. For Adam (2004, p. 50), this article clearly states the precedence of the *Official Languages Act* over all other incompatible articles or dispositions of all other laws in Canada, except the Canadian Charter of Rights. In situations where commissioners did in fact express opinions or concerns in areas outside their jurisdiction, members of parliament could and did question their personal authority to go beyond their mandate. The legitimacy of the commissioners over-reach, however, is ultimately judged by public opinion (Adam, 2004).

The Office of the Commissioner of Official Languages is an important element to Canada's national language policy implementation and development. For 40 years since the adoption of the *Official Languages Act* and the creation of the Office of the Commissioner of Official Languages, the annual reports have shed light on the accomplishments, the improvements and what needs to be done to meet the objectives of the *Official Languages Act*. But, as Fraser highlights in a 2010 news release (OCOL, 2010), the federal public service continues to wait to react to complaints before ensuring compliance with the *Official Languages Act*, rather than act proactively. Resistance seems to persist. The need for the Office of the Commissioner of Official Languages remains.

The Office of the Commissioner of Official Languages is no longer Canada's only ombudsman for official languages. Four other provincial and territorial jurisdictions, New Brunswick, Ontario, Nunavut, and the Northwest Territories now have their own provincial commissioners to watch over, guide, and support the implementation, planning, and policy development of official bilingualism at the provincial level. The five commissioners met as a group in August 2010. As we look to the future, collaboration and support across jurisdictions for the implementation of the official language policies seems plausible, possible, and desirable, in line with the objectives of the *Official Languages Act*.

Candlin, Christopher N.

RODNEY H. JONES

Christopher N. Candlin (1940–) is a major figure in applied linguistics, particularly in the areas of communicative language teaching and professional communication. He holds a BA in modern languages from Oxford, an MPhil in linguistics from Yale, and an honorary PhD from the University of Jyväskylä, Finland, and has held teaching and research posts at the University of Leeds, University of Lancaster, Macquarie University, City University of Hong Kong, and the Open University (UK). He has also held visiting and honorary professorships at a number of institutions including the University of Hawai'i, the East-West Center, Ontario Institute for Studies in Education, and University of Cardiff. Concurrent with these posts he established a number of important research institutes and centers including the Institute for English Language Education at the University of Lancaster in 1976, the Centre for Language in Social Life at the University of Lancaster in 1983, the National Centre for English Language Teaching and Research (NCELTR) at Macquarie University in 1987, which was a Commonwealth Key (National) Centre for Teaching & Research, and the Centre for Language in Social Life at Macquarie University, Sydney in 1994. He served as head of the department of linguistics and modern English language at the University of Lancaster between 1980 and 1983. He is currently senior research professor at Macquarie University. He has also been an important force in publishing in applied linguistics, editing 11 international book series with such publishers as Oxford University Press, Addison Wesley Longman, Routledge, and Palgrave Macmillan.

Candlin's most influential early work centered on defining the field of communicative language teaching and formulating principles for the design of communicative curricula (Breen & Candlin, 1980; Candlin, 1981, 1989). In this work he argued that communicative language learning involves learners being socialized into new kinds of social roles and social identities while at the same time drawing on a range of competences they already have based on communication in their native language and culture. Thus, curriculum design is an essentially reflective and critical process (Candlin, 1984) of facilitating a negotiation between the target repertoire and the abilities and expectations of learners. Related to his work in communicative language teaching, Candlin also made a significant contribution to the theory and practice of task-based language learning (Candlin, 1987b; Candlin & Murphy, 1987), devising a framework for organizing language-learning tasks based on various systematic components including goals, input, setting, activities, roles, and feedback.

In the later part of his career Candlin became increasingly involved in the study of professional communication, especially in the areas of law and medicine, an interest which began as far back as the mid-1970s with his work on developing language curricula for overseas doctors and medical staff (Candlin, Bruton, & Leather, 1975). In many ways his research in these areas helped to define the role of applied linguistics in the domain of professional communication and demonstrated the ways that linguists and discourse analysts can engage in fruitful collaboration with institutional and professional members. Not only has this work resulted in a wealth of findings directly applicable to the refinement and improvement of professional practices in a range of disciplines, but it has also yielded a number of important insights about discourse in social life relevant to other settings.

Among these is the notion that communicative situations, especially in institutional and professional contexts, often involve “critical moments” in which issues of power, rights, claims, and responsibilities are critically evidenced, and in which discursive competence is particularly consequential (Candlin, 1987a). Observing such moments is of particular value for analysts, for it is in “critical moments” that the relationship between professional practices and the discursive practices which either support or undermine them become especially apparent.

Another of Candlin’s important contributions has been in the study of the strategies professionals use to control communication processes and outcomes and define situations in particular ways. Most of these insights have come from the study of the discourse of alternative dispute resolution (Candlin & Maley, 1994, 1997), in particular how mediators use *reformulations* to reframe situations by altering experiential, interpersonal, and textual aspects of the message, and how they draw upon the discourses of other professions, specifically law and therapy, to create effective “inter-texts.” In this work Candlin demonstrated that strategic uses of language in such settings are, as he puts it, the “interpenetration points, par excellence” for the study of intertextuality and interdiscursivity (Candlin & Maley, 1994, p. 79).

More recent work has focused on the discursive construction of risk and expertise, especially in health-care settings (Candlin & Candlin, 2002), demonstrating how the quality of health outcomes is directly related to the quality of discursive encounters between professionals and lay participants.

Candlin’s research both in English language teaching and learning and in professional communication has resulted in numerous concrete benefits for professional practitioners and their clients, patients and students, and paved the way for future work on the relationship between discourse and professional practice.

Carroll, John B.

PETER SKEHAN

John (Jack) Bissell Carroll was a psychologist interested in language who had immense impact, both within his own field and also in applied linguistics. He was born in Hartford, Connecticut, in 1916, attended Wesleyan College for undergraduate work, and then completed a PhD at Minnesota in 1941, also working with L. L. Thurstone at the University of Chicago. He held academic posts at several universities, but most importantly in the Graduate School of Education at Harvard, and as William R. Kenan Professor of Psychology at the University of North Carolina. He also worked for a time at the Educational Testing Service (ETS). He died in 2003, aged 87.

His contributions are enormous and diverse. But we can start with his own central concern. Jack Carroll linked his interest in language with impressive knowledge of multivariate statistical techniques. He was fascinated by individual differences, and the structure of abilities, particularly the way language abilities fitted into the wider picture of cognitive functioning. His first significant publication was "A Factor Analysis of Verbal Abilities" (1941); his magnum opus, published in 1993, was *Human Cognitive Abilities: A Survey of Factor Analytic Studies*, demonstrating remarkable constancy in the nature of his interests. His 1993 book put forward a three-stratum view of human cognitive functioning, working from one general intellectual functioning factor, to a second stratum of broad ability domains (e.g., reasoning, verbal abilities, memory abilities), to a third more detailed stratum with more specific factors such as verbal comprehension, phonetic coding, vocabulary (all within verbal abilities). All this was meticulously supported through a meta-analysis of 461 data sets.

In considerable contrast, when Carroll was just 13 he attended a lecture by Benjamin Whorf, sparking an interest in Whorf's work on cultural relativity, and leading to a personal friendship. This led to a considerable growth in Carroll's knowledge of linguistics, and he retained contact with Whorf, collaborating with him on language work, and culminating in Carroll's editing of Whorf's work in *Language, Thought, and Reality: Selected Writings* (1956). At around the same time, he participated in conferences organized under the aegis of the (US) Social Science Research Council which culminated in Osgood and Sebeok's (1954) *Psycholinguistics: A Survey of Theory and Research Problems*, a volume which was foundational for the emergence of the subfield of psycholinguistics. Another distinct, and typically prescient contribution to applied linguistics was Carroll's work (from his time at ETS) in the production of the *American Heritage Word Frequency Book*, a significant educational contribution in providing frequency data that was linked to the effectiveness of educational decision making, and which foreshadowed work in corpus linguistics. He specialized in the statistical underpinning of the research, looking at how information from different corpora could be combined, and how inferences could be made that go outside the specific corpus that is being analyzed (Carroll, Davies, & Richman, 1971).

These general achievements set the scene for Carroll's three more specific contributions to applied linguistics. These are to educational linguistics, to language testing generally, and to the area of language aptitude measurement and theory. His contribution to educational linguistics was the publication of his seminal "A Model of School Learning" paper in 1963. The model combined individual difference factors (e.g., aptitude, motivation) and

instructional factors, and explored how these two sets of influences could interact, thus anticipating the condition-seeking, interaction-oriented research that is now more commonplace. In other words, while individual differences were important in this model, a major contribution was to bring out how these differences could be compensated for by appropriate instructional decisions, sensitive to the needs of individual learners.

Carroll's contributions to language testing are wonderfully diverse. Practically, he directed an extremely important international survey into the teaching of French (Carroll, 1975). This was ground-breaking, making the development of standardized measurement procedures central, and explored how measurement in eight different countries, with clearly different educational environments, could be conducted in a manner that allows international comparisons. Carroll also made contributions to foreign language testing theory. In an early article on cloze testing (Carroll, Carton, & Wilds, 1959), he concluded that the format did not have considerable potential, since the processes that it uses are primarily local in nature. He also theorized language testing in interesting ways. First, he was less interested in "systems" for analyzing tests, for example, skills-by-levels matrices, and instead focused on processes that underlie language performance. Second, he stressed the importance of integrative testing, rather than the atomistic approach which was perhaps more typical at the time of his interest in language testing. These concerns are expressed in an influential article published in 1968, "The Psychology of Language Testing," in which he explored the significance of a competence–performance distinction (and of nonlinguistic influences on test scores), of the importance of individual differences in their potential for interaction with testing formats, and of the importance of analyzing test formats. Carroll also contributed an interesting chapter to the debate on the unitary competence hypothesis, which raged during the 1970s (Carroll, 1983). He demonstrated that a single factor solution to batteries of language tests (implying a unitary competence) could easily emerge if inappropriate analyses were conducted. The chapter is a clear tutorial about the importance, for factor analytic studies, of the careful consideration that is needed as to which tests or measures to include, and how to analyze the resulting dataset.

But it is Carroll's work with foreign language aptitude that is the most distinctive and enduring. With Stanley Sapon (Carroll and Sapon, 1959) he published the Modern Languages Aptitude Test (MLAT), a general purpose, omnibus test battery to measure language learning ability. The manner of developing this test battery is as interesting as the battery itself (Carroll, 1962). Carroll developed over 50 potential aptitude tests. Some predictor tests were then eliminated because, simply, they did not correlate with achievement. But the successful predictors were submitted to a factor analysis. This had two outcomes. Tests identified as duplicating one another could be eliminated. The factor analysis also demonstrated that four factors seemed to underlie the relations between the different tests. These were phonemic coding (the ability to analyze sound so that it could be retained for more than a few seconds); grammatical sensitivity (the talent to identify the functions that words fulfill in sentences); inductive language learning ability (the capacity to take a corpus of a target language, analyze it, and then form generalizations and extrapolate as to how new utterances could be produced in a rule-governed way); and associative memory (the ability to make links between verbal pairs of elements). The MLAT arose from this research foundation, and has been the most influential foreign language aptitude test of all time. It has been extensively validated, and has norms that facilitate interpretation. It has been translated and adapted for many languages. It was most influential in the 20 years of so after its development (Carroll, 1973). Subsequently, it lost favor somewhat, and was associated with outmoded, audiolingual methodologies. Indeed, it went out of print for a time, but is now available again.

The more recent reassessment of Carroll's aptitude work is very interesting. Two factors may be relevant. First, there is now a wider appreciation of the importance of individual

differences in language learning. It is less common to assume that all learners are the same, and so research studies now are far more likely to differentiate between learners, and even explore learner–treatment interactions. Second, Carroll’s four-factor aptitude theory has been seen to have relevance for contemporary issues of dyslexia, of acquisition, and of the first–second language acquisition comparison. Phonemic coding ability, for example, has been shown to have links to procedures used to measure (native language) dyslexia. More process-oriented approaches, which examine a learner’s capacity to identify interlanguage generalizations, recognize that not all learners operate acquisitional processes in the same way. For example, Robinson (1996) has explored how different instructional conditions link to (MLAT-based) measures of aptitude. Others have explored issues such as whether first language processes are implicit, while second language processes are explicit, and have used MLAT-based measures to cast light on critical period effects. Most recently, Abrahamsson and Hyltenstam (2008) have argued that second language learners who defy critical period limitations are learners who are equipped with very high aptitude.

Of course, there are limitations to Carroll’s aptitude work. With the language-oriented subtests there is little theoretical foundation, and future research needs to show how what is measured is grounded in acquisitional theory. In addition, there is insufficient emphasis on proceduralization issues (although this is difficult to build in to what are relatively brief tests). And most glaringly, memory research has developed apace since Carroll’s development of a fairly limited associative memory test. There is nothing, for example, on working memory (unless one designates the phonemic coding ability factor as addressing this area). But set against these limitations, Carroll entirely shaped the way we think about aptitude, and the ways we research it. He has left us concepts and measurement tools that are still highly relevant, more than 50 years after they were developed.

Case Study

PATRICIA A. DUFF

Defining Case Study Research

Case study is a very common and important approach to research in applied linguistics and many other academic and professional fields. Case studies are frequently qualitative and interpretive, but they can also be combined with, or can include, quantitative analyses and other approaches to knowledge generation. Case studies generally involve rich contextualization and a deep, inductive analysis of data from a small set of participants, sites, or events in order to understand aspects of language learning or use. Sometimes the focus of study is the knowledge, performance, or perspectives of a single individual, such as a language learner or teacher. Other types of case study may focus less on the individuals involved and more on a single speech event, activity, institution, policy, country, or scenario in which particular language issues figure prominently and are the focus of analysis. Regardless of what constitutes the case (a person, site, or situation), by definition, one or more *single bounded units* are selected for study because of their complexity, the types of interactions among their constituent parts, or how the cases relate to existing knowledge or theories about the way language operates in the world. The cases may confirm, disconfirm, complicate, illustrate, describe, explain, or extend existing knowledge in a variety of ways and drawing on a variety of epistemologies and theoretical and methodological frameworks. Despite the range in types and purposes of case studies, one commonality is that they provide concrete instances of a phenomenon of interest.

Case Studies in Applied Linguistics

Case-study research has played a crucial role in applied linguistics across a wide range of subspecializations, from second language acquisition (SLA) to pragmatics, studies of bilingualism and multilingualism, workplace communication, language policy, classroom pedagogy, or linguistic-landscape research in a particular region. One reason case study can be so compelling is its seeming simplicity and singularity. By examining quite intensively the experiences or characteristics of just one or a few people or contexts, researchers aim to understand in a more holistic way (usually) the intricacies and inner workings of the people, events, systems, or policies under scrutiny. The case then becomes a vivid exemplar of larger processes and conditions related to language. Although generalizations from the observed cases to all other cases in the same class, set or population (e.g., all students from a particular linguistic background, all workplaces, all classroom instruction) are neither desired nor possible, case-study research does have the potential to generate analytic generalizations, providing implications for models or theory (Duff, 2006). In addition, because fewer participants or sites are involved (typically) than in many other types of applied-linguistic research, a greater degree of contextualization can be included, and the complexities of the interaction between participants and their social, political, educational, or interpersonal situations can also be explored more fully. However, there are inevitable tensions and trade-offs in seeking local, highly situated understandings of particular

2 CASE STUDY

phenomena versus trying to derive more general principles about applied linguistics and about humans' capacity to learn, use, or negotiate language. One challenge for case-study researchers, then, is to highlight the particularities of cases and contexts but also derive broader principles or observations of relevance to the field or to other readers beyond the specific cases in question.

This entry presents a brief overview of case studies in applied linguistics. Duff (2008, especially chap. 3) provides many detailed examples of research questions and studies that have characterized different decades of research, especially in L2 learning and education. In the same book, the philosophical underpinnings of case-study research are described in more depth and practical advice is given about conducting and reporting on case studies. Rather than reproduce that earlier material or studies featured in Duff (2012), this entry will profile other recent case studies from a variety of publications and types of research in order to help illustrate principles of case-study research.

The journals *Applied Linguistics*, *Journal of Language, Identity, and Education* (JLIE), *Journal of Second Language Writing*, *Modern Language Journal*, and *TESOL Quarterly*, among many others, often publish case studies nowadays, although that has not always been the case. A recent special issue of JLIE (Block, 2008a), for example, was titled *Multilingual Identities and Language Practices in a Global City: Four London Case Studies*. In a sense, the entire special issue constitutes a case study of multilingualism in one of the world's most cosmopolitan and multicultural "global" cities, and follows up on earlier work and larger studies by Block and his contributors on this same theme. The "case studies" in the special-issue volume included Block's (2008b) own study of Spanish-speaking Latinos (SSLs) in London, one particular community (albeit a fragmented one, as he points out) or case. He includes a discussion of census data and other publications about Spanish speakers in London over the past generation, and then describes the experiences of a subset of SSLs (four out of eight in total) he had interviewed and reported on elsewhere in more depth, all with respect to his underlying question of whether the SSLs in London constituted a cohesive community. It is therefore a kind of *nested* case study: The city is a case (of urban multilingualism, of a "global city"); the Spanish-speaking population in London is another case, illustrating the larger theme; and then profiles and data from four interviewees (focal cases) are included, revealing that they seem to represent a kind of "invisible minority" in London in this "emergent" community.

The second "case" in the special issue, by Cooke (2008), features a different demographic: youth migrants in London struggling with their "identities, positionings and education" (p. 22), in part because of the mandated national English-language curriculum, which was designed for adults, not teenagers. The focal participants (cases), all male, include a Kurdish Iraqi, an Angolan, and a Portuguese of African descent. The broader thematic case is the challenges facing adolescent visible minorities who are English-language learners and new urban settlers, two of whom are asylum-seekers, all negotiating their legitimacy and aspirations for their new lives in London.

The third study, by Preece (2008), is a "case" of multilingual, female, mostly British-born South Asian undergraduates at one university in London negotiating and performing discourses surrounding gender identities and heritage languages. Participants included a dozen females who took part in peer discussion groups and interviews, originally as part of a larger dissertation study. Thus, the "single bounded unit," apart from the university and city in which the study took place, and the academic writing program in which the author originally met them, appears to be the unit or situation of "urban ethnic-minority female university student," although diversity clearly exists among the members of this group.

Finally, Wallace's (2008) case study focuses on "identity construction of young people of minority ethnic background" (p. 62), particularly in relation to talk about literacy in classroom settings (two younger and two older children in each of two London schools).

Among aspects of the bilingualism, identity, and literacy practices she investigated, religious identity and associated language practices were foregrounded.

Thus, all four studies in the set were situated in London and revealed linguistic and social aspects of multilingualism and migration there, but the participants, units of analysis, linguistic and literacy issues, and theoretical frameworks and constructs used to describe the populations and their perspectives differed according to each author's purpose. None tried to generalize from their findings to other global cities or to the wider populations from which they had drawn their focal participants. However, they successfully illustrated some of the tensions commonly reported in urban, multilingual diaspora settings, with London constituting a unique sociological setting for this particular cross section of English-language learners and bilinguals. By aggregating four "cases" from the same city (another level of case), the volume gives readers an appreciation for the linguistic pluralism and socioeducational issues facing many youth and young adults in that context, one that could then be compared with other global cities.

An online search of other recent applied-linguistic case studies generates an enormous number and range of books, chapters, journal articles, dissertations, reports, and abstracts. However, examining recent articles in peer-reviewed applied-linguistics journals that are explicitly framed by their authors as "case studies," like the special issue reviewed above, is quite telling. For example, Abrams (2008), Barkhuizen (2009), Barnard (2009), Han (2009), Li and Schmitt (2009), Menard-Warwick (2008), Storch and Wigglesworth (2010), and Waring (2009) investigated an assortment of issues, but all opted to not only use case-study methodology but also foreground "case study" (or "single case") in their titles. The studies themselves featured, as cases, international or immigrant students, foreign-language students or teachers, or immigrant entrepreneurs. But the phenomena examined in and across the cases included such topics as questioning patterns, vocabulary acquisition, the effects of corrective feedback on writing, language teachers' histories, identities, and practices, and appropriate curricular accommodations for L2 students with learning disabilities.

Sometimes, rather than include "case study" in their titles, as these studies did, phrases such as "a longitudinal study" or "two students" (or "a classroom in Ghana," "two Canadian workplaces") indicate the nature of the case and its boundaries. However, it can be difficult to discern from titles or abstracts whether a case study is indeed being reported on or what the case is about, although normally that information appears in a section on research methodology or context. The authors should explain what the study is a case of and not only the number and description of participants or sites where the study takes place (Duff, 2012). Some publications with the term "case study" in the title may include just brief examples or vignettes of a phenomenon, or refer to the reported study as a case (e.g., of an experimental intervention or a survey), but without the contextualization, triangulation, in-depth analysis of data, and interpretive practices and discourse that are the hallmark of much qualitative case-study research. Researchers are therefore advised to use and interpret the term "case study" with caution, as it technically refers to a particular type of research design and written report and increasingly is also associated with an interpretive, qualitative epistemology.

Corresponding with the growing popularity and acceptance of case studies in applied linguistics and the growing awareness that an ecological, socioculturally situated analysis of a wide variety of linguistic and personal phenomena (such as identity) offers many theoretical and interpretive advantages over less situated accounts, a wider range of populations, sites, and languages is now being researched. Increasingly, these include asylum-seekers, often with very complicated transnational and linguistic histories, multilinguals of all ages and descriptions, heritage and indigenous language (re-)learners or users, younger learners and older learners (or users), illiterate, multiliterate, and multimodal language users, members of Deaf or signing communities, Generation 1.5 immigrant

populations and multinationals, and individuals performing gendered and other social identities in particular discursive ways. This broadened purview of case studies and the populations and topics being researched is both important and healthy for the field of applied linguistics because it allows commonly held understandings about the processes of, and conditions for, language teaching, learning, assessment, and use and about population traits and variables to be challenged and reconceptualized based on evidence from other, previously unresearched or under-researched settings. In addition, new technologies for investigating language practices and processing, in case studies of language use in virtual communities, studies involving brain scans, or various other contexts, also involve and yield new tools, methodologies, and theoretical understandings for the field.

As in the “four London cases” described earlier, we learn from such accounts about the diversity of language users around the world, about their communities, ideologies, identities, and practices, about problems with essentializing (overgeneralizing from) certain categories of learners, and about the impact of globalization on migration, education, and linguistic behaviors. Sometimes it is only by means of comparisons of such studies with studies situated in other locations (e.g., the “global cities” of Mumbai or Montreal) or in readers’ own contexts that their uniqueness or typicality—or the particular combination of factors affecting linguistic phenomena—becomes apparent, leading to the *transferability* of findings. Readers learn about issues likely to be of wider social, educational, and linguistic significance in the world, particularly if they feel confident that the researcher’s case study is credible and trustworthy, is well supported and illustrated with relevant data or evidence, and also, ideally, attempts to make links between the local issues reported on and those of wider interest in applied linguistics or in other relevant disciplines.

Issues in Case-Study Research

Many case studies in applied linguistics—although not nearly enough—are longitudinal, lasting typically a few months to a few years, particularly if the study is part of major funded institutional research or dissertation or thesis work. For developmental studies, this mid- to longer-term perspective can be extremely helpful and can demonstrate, for example, interim stages in learning and how certain developmental patterns relate to other patterns or behaviors. In other areas of work, such as language policy and research on language shift, a longer-term perspective may be essential for understanding local linguistic ecologies, educational practices, the politics of language choice, and nonlinguistic factors affecting policy development and implementation. Longitudinal work can be very rich indeed, revealing migration patterns, attrition in language programs or schools (e.g., non-completers, transfers, or dropouts), language learners’ and users’ complex histories and trajectories, and sociopolitical and educational change. However, longitudinal work can be very demanding, precisely because research populations in applied linguistics may be quite migratory, people may leave work or education programs for a variety of reasons, and because researchers are under institutional pressure to produce shorter-term research results for annual productivity reviews (Duff, 2008; Harklau, 2008).

How many cases should be included in a study—a single case or several cases? As is explained elsewhere (Duff, 2006, 2008), there may be very good reasons for focusing on just one case (an event, school, person, family) rather than several. It may provide sufficient detail and evidence of the phenomenon under investigation, it may serve as a pilot study, or may be highly representative of others in a larger study and serve as an exemplar. Conversely, it may be quite distinct from other cases in the larger study and for that reason warrant special attention. Space limitations and the desired scope of an anticipated publication might also preclude the inclusion of more cases since the researcher would be

unable to provide sufficient details to fully illustrate the issues being investigated. One case in such instances might be quite adequate.

However, multiple-case studies, if done well, can provide a much richer account of the phenomenon in question by revealing similarities, differences, and variation in the observations and experiences of participants (or sites). The multiple observations then help researchers describe—and theorize about—the conditions under which certain cases seem to behave or perform in particular ways and not others. For larger-scale studies such as doctoral dissertations, therefore, there are many advantages to including several (e.g., two to six) cases for in-depth study rather than just one. When more than one case is included, authors have various options about how to present the findings. Individual cases can be described, followed by a cross-case analysis. Alternatively, the report may be theme-driven with data drawn from cases as is relevant. Yet another option is to group cases according to certain shared (thematic or demographic) features, presenting them not as individuals but as pairs or small sets of cases that are then compared with other pairs or small sets.

It is nevertheless important to explain why particular cases (and not others) were included, how data analysis was conducted, and how findings have been represented. If the report is drawn from a larger study involving several other cases, readers normally want to know how the featured cases differ (if at all) from others in the set or why they have been singled out for publication in a particular piece. Qualitative case-study researchers do not always seek or select cases that are highly representative of the larger sample or population from which they are drawn. As was mentioned above, they may intentionally sample for extreme, atypical, or unusual cases to illustrate a phenomenon. However, readers and reviewers often wonder about the typicality or uniqueness of such cases, of counterexamples or outliers in the larger set, and about what kinds of inferences can be drawn from these particular cases in order to understand the phenomenon in question. Therefore, researchers must describe sampling and selection criteria very carefully—the rationale for the recruitment or selection of particular types of cases rather than others—and consider the implications of such decisions and then the findings based on them for the field more generally. Because applied linguistics research normally depends on the voluntary participation of research subjects, it is also important to consider how the self-selection (volunteering) process itself influences the types of participants in the study and the findings that emerge. Are these participants more confident, optimistic, proficient, available, or needy (e.g., when a financial incentive is offered) than others targeted for recruitment who opted *not* to participate? How might the participating subjects' personal characteristics or demographics delimit insights into the issues or experiences being investigated?

The same principles and questions apply to the selection of transcript material, activities, images, examples, and other forms of data included in an article. Readers deserve to know how and why particular examples were chosen and how representative or typical they are of the larger data set.

Finally, case-study researchers often need to pay special attention with respect to research ethics and confidentiality precisely because the more in-depth and contextualized the case, the more details about the participants and setting are revealed and thus the more potentially identifiable it will be (Duff, 2008). Also, the closer the case participant is to the researcher, or the more closely the researcher is involved in a power relationship with potential participants, the more questions arise from ethical review boards about the appropriateness of recruitment. A common concern is whether the participant can truly offer informed consent (assent, in the case of minors) without feeling coerced. Furthermore, review boards seek assurances that participants are fully competent to understand the study's objectives and methods, and their role in it, in order to provide

their truly informed consent. In cross-cultural and crosslinguistic research, often with disadvantaged populations, this principle is very important and often necessitates providing multilingual paperwork and oral explanations about the nature of research projects and participation in them.

Case Studies in Mixed-Method Research

The theoretical philosophy underlying case-study research, as a method, is that much can be learned by looking both holistically and in close detail at the behaviors, performance, knowledge, or perspectives of just a few rather than many research subjects. The cases can reveal important developmental patterns or perspectives that might be lost or obscured in a larger-scale study of populations or larger sample sizes, especially where measures of central tendencies (the average or normative experience) are reported. The local contexts and conditions can be fleshed out much more fully than would be possible with a large number of participants and contexts that would normally rely on quantitative methods to describe patterns and changes because of the sheer volume of data. These patterns or insights then contribute to theorizing about the phenomenon under investigation. However, including the backdrop of larger patterns, including typical experiences, also helps with the contextualization and interpretation of individuals' experiences. There is, therefore, a natural potential synergy and complementarity between universalizing and particularizing approaches to research. Mixed-method research incorporating both quantitative and qualitative approaches, for example, has not been used to a great extent in applied linguistics historically, perhaps because there was often a mutual aversion on the part of researchers toward paradigms other than the primary ones guiding their own work or toward the usefulness of different ways of capturing and presenting data. Fortunately, in recent years important strides have been made in attempts to bring together the strengths and affordances of different methodologies and traditions to produce robust studies that can often benefit from a combination or triangulation of methods, theories, disciplinary perspectives, researchers, and data.

Recent multimethod research with (variably longitudinal) case studies in SLA includes Caldas (2007), Donato and Tucker (2010), and Kinginger (2008) (see Dörnyei's 2007 chapter on multimethod research for other references). These scholars combined proficiency tests or social-psychological measures based on questionnaires about learners' attitudes and motivation with case studies of children's, bilingual adolescents', or L2 study-abroad students' experiences of learning another language (French in Caldas's and Kinginger's studies and Japanese in Donato and Tucker's), or being socialized into another culture and how it affected them, their proficiency, identities, and so on, often over an extended period. The larger quantitative data provides very useful background information against which cases can be foregrounded, which helps address questions by readers or reviewers about scope, scale, and representativeness. The qualitative case studies also personalize or animate more technical or abstract statistical descriptions of observed trends, behaviors, practices, or populations. Another option is to keep case studies at the core of the research but to invite researchers embracing different theoretical frameworks, disciplines, or research methodologies to examine the same cases, leading to a potentially richer triangulation of perspectives than viewing cases from one primary perspective alone.

Conclusion

Case-study research has much to offer both applied linguists and nonspecialists attempting to understand scholarship in our field. It is now seen to be a valued and valid approach

to research in education, sociolinguistics, pragmatics, assessment, and other strands of applied linguistics, especially when it is conducted and written up well. As revealed by the citations above to recent case studies in applied linguistics, case-study research can be longitudinal and ethnographic or it can be much shorter in duration, less sociocultural, and more technical and narrow in focus in terms of linguistic or cognitive processes or systems. It can stand alone as research or can be combined with other research methodologies and designs. Case-study research in education tends to be inductive and interpretive, seeking recurring patterns and themes for the purpose of gaining understandings of different experiences. But some case studies, for example those in psychology or linguistics, may be more deductive, positivist, and quantitative, testing hypotheses about cause–effect relationships or other interactions among variables. Regardless of the underlying epistemology and ontology and the tools used for data collection and analysis, the primary benefit of case studies is that they provide a window into the worlds of people and linguistic events. Effective case studies are accessible and informative for readers because of the narrative or expository description and contextualization provided about the individuals or sites and the phenomena of interest. It is for this reason that case studies are often a key component of instruction and assessment in law, medicine, and business, and they have the same pedagogical merit and potential for knowledge mobilization in applied-linguistics programs and publications as well.

Catford, J. C.

JIMMY G. HARRIS AND JOHN H. ESLING

Professor Emeritus J. C. Ian Catford was born in Edinburgh, Scotland, in 1917 and died peacefully in Seattle, Washington, in 2009. Ian's father was English and his mother was Scottish. He grew up in Edinburgh and considered himself more Scottish than English. In his preteens, he was seriously interested in engineering, especially the aerodynamics of steam flow, steam valves, and cylinders of steam locomotives.

In 1931, at the age of 14, his parents took him to see a stage performance of George Bernard Shaw's *Pygmalion*, which impressed him enormously and caused him to be deeply interested in linguistics and phonetics for the rest of his life. Later on, while browsing in an Edinburgh secondhand bookstore, he bought a copy of Henry Sweet's *A Primer of Phonetics*. He stated that the primer became his bible and caused him to read everything on the subject in the Edinburgh Public Library.

In 1933, through a friend, he met Daniel Jones of University College London (UCL), who put him through a short oral examination on practical phonetics, asking him to pronounce all manner of sounds including back unrounded vowels, ejectives, and implosives. He passed the exam and went on to study Jones's pronouncing dictionary of RP English until he became fluent in RP (received pronunciation). In the summer of 1934, he took a course in French phonetics at UCL. His teachers were Hélène Coustenoble and Lilius Armstrong. He also took an instrumental phonetics course from Stephen Jones. Daniel Jones gave him private instruction in the cardinal vowels and the phonetics of Urdu. In addition, he studied notebooks from the mid-1930s containing phonetic notes on Norwegian, Dutch, Serbo-Croatian, Japanese, Persian, Sindhi, Derawal, Urdu, Telugu, and many dialects of English.

In 1935, at age 17, he gave a talk on Scottish dialects on the BBC (British Broadcasting Corporation). At about this time, the BBC hired him to participate in radio plays as a specialist in exotic and foreign language accents. He thus began a long association with the BBC and broadcasting in general. Also in 1935, he published his first phonetic publication on a Southern Scots dialect in *Le Maître Phonétique*. That summer he went to Paris to perfect his French pronunciation. Many French people he spoke with thought he was French because his accent was so good.

While in Paris, he met Paul Passy, the famous French phonetician and one of the founders of the IPA (International Phonetic Association). Back in London, he attended the Second International Congress of Phonetic Sciences, where he met Otto Jespersen and H. E. Palmer. He later entered the University of Edinburgh where he majored in French. He spent his third year in 1938 in France where he studied phonology with André Martinet. At the end of his year in France, he attended the third International Congress of Phonetic Sciences, where he got to know Hjelmslev, Trager, Jon and Betsy Uldall, Eli Fischer-Jørgensen, Jespersen, Paget, and Jakobson.

In 1939, his article "On the Classification of Stop Consonants" was published. Back in Edinburgh, he took a course in Sanskrit and became convinced that all students of linguistics should study Latin, French, and Sanskrit. In 1939, he went abroad to Greece to teach basic English for the British Council. His colleagues in Athens were David Abercrombie

and Jon and Betsy Uldall. During his two years in Athens he acquired a working knowledge of modern Greek. He also worked on his first Caucasian language—Kabardian (1942). With the German army approaching Athens, they were evacuated to Egypt, where he worked on another Caucasian language with a refugee who spoke Avar (1943), a Dagestanian language.

In 1943, he was transferred to Palestine where he taught English to speakers of 60 different languages. He also married Lotte Gerecht in the same year. They spent their honeymoon in Lebanon and Syria working on Circassian. Back in Palestine, he worked as a radio announcer for a radio station in Jerusalem that broadcast to Nazi-occupied Europe in 15 languages. His most important announcement in June 1944 was, “This is the voice of the United Nations from the British Mediterranean station. The liberation of Europe has begun,” following the Allied landings in Normandy.

In 1946, he finally returned to the UK where he earned his living as a BBC radio actor specializing in exotic and foreign accents, as a teacher of applied phonetics at the Royal Academy of Dramatic Art, and as a private teacher of English to foreigners. He also studied general linguistics under J. R. Firth and Slavonic Linguistics at University College London.

In 1952, he took a job at Edinburgh University as a researcher for the Linguistic Survey of Scotland. In 1957, Catford was appointed Director of the new School of Applied Linguistics (SAL) at Edinburgh University. In preparation for the job, the British Council sent him on a two-month tour of India and Pakistan to study the problems of teaching English in both countries. In his spare time, he worked on Paryabi tones, Miretané implosives, Ladakhi Tibetan voiceless laterals, and the Kannada, Toda, and Burushaski languages.

As director of SAL, Catford felt that applied linguistics should foster a wider knowledge of linguistic data and theories than other types of linguistics. It should cover a wide range of topics such as all types of language teaching, bilingualism, translation theory, dialectology, language acquisition, machine translation, developing alphabets for unwritten languages, forensic linguistics, English grammar, anatomy and physiology, general linguistics, and phonetics. He saw the study of applied linguistics as a discriminating eclecticism in which no one theory is the best for all applications.

In 1964, he was invited to join the Department of Linguistics at the University of Michigan in Ann Arbor to serve as director of the English Language Institute. He also taught applied linguistics, translation theory for TEFL (teaching English as a foreign language), comparative historical linguistics, and phonetics. In 1970, with a grant from the American Council of Learned Societies, he went to the Soviet Union where he worked on 20 Caucasian languages. In 1977, he returned to the Soviet Union where he worked on seven more. Also in 1977, he spent six weeks in Indonesia teaching translation theory to speakers of 25 different Indonesian languages. After his retirement in 1985, he continued his career as a visiting professor in universities in Turkey, in Israel, and at UCLA.

In 1977, Catford published his *Fundamental Problems in Phonetics*, which is an overview of experimental phonetics. In 1988, he published *A Practical Introduction to Phonetics*, and in 2001 the second edition of *A Practical Introduction to Phonetics* was published. This second edition is considered the best practical introduction to phonetics published in the last 50 years. Not only was J. C. Catford a pioneer in applied linguistics, but he is also widely regarded as the leading practical phonetician of the 20th century.

Cenoz, Jasone

JULIA D. BARNES

Jasone Cenoz is a professor in the Department of Research Methods in Education at the Faculty of Education of the University of the Basque Country (UPV) in Donostia-San Sebastian, Spain. Her academic interests encompass multilingualism, second (L2) and third (L3) language acquisition, bilingual and multilingual education, linguistic landscape, inter-language pragmatics, and the age factor.

Cenoz was born into a Navarran family in Pamplona in 1960. Although her grandparents on both sides were Basque speaking she was raised as a Spanish speaker, as were many of her generation. As a now fully competent user of Basque, with a son who has Basque as his strongest language, her work has done much to erase this generational gap largely imposed by Franco's oppressive linguistic policy in favor of Spanish.

Given the role that her work has played in the understanding of multilingual education it is significant that she studied two language degrees, completing English in 1982 at the Universidad de Salamanca, after which she carried out postgraduate work at the University of Southern California. In 1983–4, back in the Basque Country, she became involved with teaching on the University Studies Abroad Consortium at the University of Reno. Employment as a secondary school teacher of English from 1984–92 then gave her valuable practical insights into the nature of education to shape her future academic work and it was during this period that she graduated in Basque and completed her pre-doctoral studies and PhD dissertation on the teaching and learning of English as an L2 and L3 (1992).

The appearance of her early seminal PhD dissertation on multilingual education in minority language contexts, assessed by Fred Genesee and Miguel Siguán among others, coincided with the 1992 Spanish Education Reform in which English became compulsory from age 8 and was introduced in the Basque Country through experimental programs at even earlier ages. Much of Cenoz's principal research in the late 1990s would be in this field.

Also in 1992 Cenoz joined the Department of English and German Philology at UPV as a tenured lecturer through the field of intercultural pragmatics. Her undergraduate and postgraduate courses (taught in any of her three languages) in second language acquisition, linguistics, pragmatics, and sociolinguistics were popular and well subscribed and led to her supervising doctoral dissertations in a variety of fields of multilingualism such as metalinguistic awareness, writing skills, and infant acquisition among others.

Meanwhile Cenoz embarked upon various research projects attracting important funding and international interest. One of the major projects funded (1996–2004) by the Spanish Ministry of Education and Science involved the large-scale collection of data in English from trilingual cohorts who had been exposed to English at different ages to see if the age of exposure was significant. This bank of data provided invaluable resources for a number of significant doctoral dissertations. Along with other colleagues in the department she founded and subsequently led the group Research in English in Applied Linguistics (REAL), which became one of the key research teams in social science in the Basque Country and in Spain with cutting edge research in second language and multilingual acquisition,

phonology, and the age factor (Cenoz, 2003a, 2003b; Gallardo, García Lecumberri, & Cenoz, 2006). Cenoz characteristically generously contributed time and energy to building opportunities for research and an ethos of collaboration between colleagues and with other national and international universities.

National and international networks have been central to Cenoz's academic contribution whether for research, meetings and conferences, or publications. She has led initiatives to bring together communities who share similar linguistic issues, from classroom practitioners to academics. Language professionals everywhere will recall conferences, meetings, workshops, and summer courses with expert speakers from many fields of bi- and multilingual education, pragmatics, research methods, and so on, held under Cenoz's supervision often in the privileged sea-view locations of the Kursaal or Miramar Palace in Donostia-San Sebastian, or the seminars organized by the REAL group in Vitoria-Gasteiz, and elsewhere. Key events have been the 1999 International Association of Child Language (IASCL) conference and the 2004 European Association of Second Language Acquisition (EUROSLA) conference. Cenoz herself has been much in demand as an expert speaker receiving invitations to lecture in locations as diverse as Israel, Poland, the United States, India, and Australia. She has also been a consultant to the European Commission and for the Spanish University National Accreditation Commission as well as an assessor on numerous PhD boards.

The potential of her early work was acknowledged with two key books in the field edited in collaboration with Fred Genesee (Cenoz & Genesee, 1998, 2001) which were to provide a window to work on education and language acquisition at the end of the millennium. There followed her extremely active involvement in international publication, for instance as the International Association of Applied Linguistics (AILA) publications coordinator and as member of the board between 2002 and 2008 where she continues as a member at large. She has also served on the board of journals and series such as the *AILA Review*, *Annual Review of Applied Linguistics*, *Applied Linguistics*, *International CLIL Research Journal*, *International Journal of Bilingual Education and Bilingualism*, *Journal of English Studies*, *Language Policy*, *Language Teaching*, *Vigo International Journal of Applied Linguistics* (VIAL), *Multilingual Education*, *AILA Applied Linguistics* book series, *Tertiärsprachen* (Stauffenburg), and the *Mouton de Gruyter Trends on Applied Linguistics* series.

Jasone Cenoz has been key in the establishment of the biannual Conference on Third Language Acquisition and Multilingualism which first took place in Innsbruck in 1999, and in the establishment of the International Association of Multilingualism (IAM). This association has been responsible for the consolidation of multilingual research as a field in its own right and a number of major publications have been the outcome (Cenoz & Jessner, 2000; Cenoz, Hufeisen, & Jessner, 2001, 2003). With Ulrike Jessner she is one of the founders and editors of the *International Journal of Multilingualism*.

In 2000 she gained her tenure professor status at UPV with a project on research methods in education and in 2004 was chosen to be its vice-rector with special responsibility for international affairs. In 2005 she moved from the Department of English Philology at Vitoria to the Department of Research Methods in Education in Donostia-San Sebastian. This move coincided with her deeper involvement with wider aspects of multilingualism and education not only with regard to English and internationalization, but also in relation to Basque and minority language education. There were a number of publications in Basque (Cenoz & Lasagabaster, 2005, 2006) and Cenoz edited a special issue of *Language, Culture and Curriculum* about teaching through Basque (2008), contributing two chapters. In 2009 she published *Towards Multilingual Education: Basque Educational Research from an International Perspective* in which her experience and contribution to the three areas of Basque, education, and multilingualism converged providing a long overdue compendium of research-based expertise for wider use in the field. Cenoz has also contributed to work on Basque in the

field of minority language with a number of publications (Cenoz, 2001; Cenoz & Gorter, 2008) as well as through collaboration with institutions such as the ERSC Research Institute for Bilingualism at Bangor University, Wales and the Fryske Academy in Friesland, Netherlands. In the meantime she has continued to stay abreast of developments in applied linguistics in general through collaborations (Manchón & Cenoz, 2008), a forthcoming special issue of *Modern Language Journal* on the topic of "Beyond Bilingualism and SLA," and an encyclopedia in collaboration with Nancy Hornberger (2007).

Her most recent work has revolved around a new research team based at UPV in Donostia-San Sebastian called DREAM (Donostia Research in Education and Multilingualism) and around collaboration with the Ikerbasque academic Durk Gorter with whom she has carried out ground-breaking work on multilingual linguistic landscape (2009). Cenoz and Gorter also have forthcoming publications relating to multilingualism and education in European minority languages, the diversity of multilingualism in education, and multilingual pedagogies in school contexts. In her latest book, published with Elka Todeva, Cenoz (2009) presents multilingualism from a different perspective in which speakers of multiple (at least seven) languages narrate their linguistic experiences.

It is Cenoz's quest to create a reference point for high-level international work on multilingualism and its research. Multilingualism has in the last 20 years become a major emerging issue at the heart of modern society and understanding it and training for it are crucial to education and policy throughout the world. Cenoz's academic contribution and initiatives, characterized by her vision, scope, and generosity, coincide with this period and the insights provided by her tireless research have made her a leading figure in the understanding of multilingualism today.

Central Institute of Indian Languages

UDAYA NARAYANA SINGH

The Central Institute of Indian Languages (abbreviated as CIIL) was established in mid-1969 by the government of India to coordinate between the central and state governments as well as among state language institutes, tribal research institutes and bureaus, institutions dealing with languages such as the Central Institute of English, Hyderabad (now known as EFLU), the Central Institute of Hindi, the Anthropological Survey of India, the Language Division of the Registrar-General's Office, and university departments of languages and linguistics. The proposal to establish CIIL, with a focus on applied linguistics, was first mooted in 1967 by a ministerial working group, thanks to the country's planning commission. The idea was later endorsed by a committee of top linguists in the country. Since then, CIIL (www.ciil.org) has been functioning as a clearinghouse for information on all matters relating to the development of Indian languages in this country and abroad, with an interdisciplinary research program. With dialogues established between traditional scholars of grammar and modern linguistics, it has also developed suitable interdisciplinary programs for giving linguistic orientation to social scientists and social science orientation to linguists.

The major achievements of CIIL have been its development of methods, materials, and aids for teaching Indian languages, and the conduct of language courses; these resources have also been used in CIIL's seven branches, called regional language centers (RLCs), which are located all over India. In addition, as well as correspondence courses using audio cassettes, CIIL has also developed CD-based, online, and radio-based courses in language teaching. Further, its flagship program, titled *Bhasha Mandakini*, has been able to produce over 600 television episodes to teach Bangla, Tamil, Kannada, and Marathi. The institution has paid particular attention to publishing grammars of tribal, indigenous, and minor languages of the country. Creating writing systems for unwritten languages entering into school and communication domains has been its responsibility, too. Yet another strong area of work done by the institution is in language testing and evaluation (www.ciil-miles.net), which has now developed into a major national project called the NTS, or National Testing Service (<http://www.ciil-miles.net/NTS-INDIA.asp>).

One of CIIL's original aims—namely, development of suitable translation techniques and conduct of courses for translators (www.anukriti.net)—has now graduated into a major national initiative called the National Translation Mission (NTM). Under this project (www.ntm.org.in), the emphasis is on creating a huge repository of texts in all 22 constitutional languages of India, promoting translator education, establishment of a database of translators and translation experts in the country, and establishing translation as an industry. A major aim of CIIL has been to develop corpora of Indian languages, and its initial work (reported at www.ciilcorpora.net and www.ciil-spokencorpus.net) developed into the huge Linguistic Data Consortium of Indian Languages (LDC-IL) (www.ldcil.org). Under the LDC-IL, CIIL—along with two Indian Institutions of Technology at Chennai (www.iitm.ac.in) and Mumbai (www.iitb.ac.in), the Indian Institute of Science at Bangalore (www.iisc.ernet.in), and the International Institute of Information Technology (www.iiit.net)—has worked on the creation, analysis, and uploading of different kinds of corpora and

other linguistic resources, such as speech-to-text and text-to-speech work, character recognition, and natural language processing vis-à-vis Indian languages. Both NTM and LDC-IL have generated many by-products such as dictionaries, thesauri, word-finders, common vocabulary research, and usage compilations. They have also contributed significantly to classical studies, such as the establishment of a Classical Tamil center (now to be found at <http://www.cict.in/>), an Institution at Chennai (titled CICT), and the current projects in Classical Telugu and Classical Kannada.

As is well known, 4% of India's people speak 96% of her languages, and many of these languages have a much smaller number of speakers. According to the 2001 census, there are 122 languages with at least 10,000 speakers in India, but the number of distinct mother tongues is well over 3,000. CIIL's work on at least half of these 122 languages through its LIS-India Project is significant (www.lisindia.net). A large number of India's smaller languages can be found in the northeastern states, and most of them are still in oral form. Attempts have been made to write grammars for the first time in their languages, and some of these can be seen at www.ciil-grammars.org. Textbooks have been prepared to introduce those languages into schools for the first time. The North East Language Development (NELD) program involves 15 languages covering six states: Manipur, Assam, Meghalaya, Arunachal, Nagaland, and Tripura. A major project has been undertaken for the linguistic and cultural documentation of 11 languages of Sikkim. Pictorial glossaries of Kok Borok (Tripura), Monpa (Arunachal Pradesh), and various Bhili languages (Gujarat, Maharashtra, and Rajasthan) have been completed. Sixty programs on northeastern languages on various subjects like dictionary making, orthography, cultural documentation, sociocultural studies, compilation of common administrative terminology, grammars, and multilingualism and language use are conducted every year. As a truly multi-headed organ of the Department of Secondary and Higher Education of the Ministry of Human Resource Development, CIIL:

- assimilates and distributes the fruits of its research in applied linguistics to all peer institutions,
- provides manpower for research and development in universities and institutions, provided they share the interest of CIIL, and
- houses all varieties of thoughts, theories, and practices in language sciences—often seemingly contradictory but each one having its own heritage and importance.

It has also been an aim of CIIL to promote and document the endangered languages of India, which are very much a part of India's plural cultural heritage. In the period since its foundation, CIIL has created a legend of its own by producing and archiving studies on 118 Indian languages, including 80 tribal languages; publishing 590 books and monographs, including language learning materials; and creating courses on cassettes in almost all major Indian languages. Its efforts in library automation have been achieved in record time under a project titled Bhasha Bharati (www.ciillibrary.org), and are often showcased as a model of library modernization.

The institution has had, in the 40 years between 1969 and 2009, three full-time directors: Professors D. P. Pattanayak, E. Annamalai, and Udaya Narayana Singh. The Central Institute of Indian Languages has so far been the principal government organ able to trouble-shoot all language-related debates, arguments, and issues wherever they have occurred, and has therefore fulfilled an important obligation for which it was created, at a time of intense linguistic strife in the country during the mid-1960s.

Chaos/Complexity Theory for Second Language Acquisition

DIANE LARSEN-FREEMAN

Introduction

Chaos/complexity theory (C/CT) and closely related dynamic systems theory were first proposed in the physical sciences and mathematics to explain the behavior of complex dynamic systems. The systems usually involve a large number of elements or agents, which interact and give rise to a different order of complexity at a higher level. An oft-cited example is how individual birds interact to form a flock of birds. The systems are dynamic because they are always changing, sometimes gradually, sometimes abruptly. Thus, the study of change is central to C/CT researchers. They seek to understand how change occurs and how elements or agents interact to produce it. Change in such systems is often nonlinear, which means that the effect is not proportionate to the cause. The nonlinearity is attributed to the fact that such systems are sensitive to initial conditions, a characteristic popularly referred to as the *butterfly effect*, whereby even the flapping of a single butterfly's wings in one part of the world can have an effect on a weather system in another. It is this sensitivity to initial conditions that makes complex systems *chaotic*—they can change in unpredictable ways.

Because of the complexity, the interconnectedness of the elements or agents, their dynamism, their nonlinearity, and the openness of such systems to energy from outside of themselves, change in complex systems cannot be explained through simple cause-and-effect relationships. Rather it can be said that the complexity emerges in a bottom-up way through the mechanisms of *self-organization*, whereby systems grow in complexity without being guided by an external source, and *coadaptation*, where the system adjusts or adapts to its context.

From this initial brief description, it may not be difficult to see why the influence of C/CT is growing. So many naturally occurring systems are complex dynamic ones: neural networks, social networks, the ecology of a particular locale, and so forth. Consequently, insights from the theory, really a meta-theory, have been applied to a wide variety of phenomena, including organizational development, the spread of disease or epidemiology, and language evolution. Its influence is broad because the theory affords a unique perspective into dynamic systems, which has had the effect of shifting our understanding of the nature of second language acquisition (SLA; Larsen-Freeman, 1997).

Traditional views of SLA

Traditional views of SLA differ in many ways from that inspired by C/CT. Many scholars date the origin of the modern study of SLA to the late 1960s or early 1970s. The field has, for much of its brief time in existence, operated under a number of assumptions, which SLA researchers have inherited from linguists and from first language acquisition researchers. These assumptions revolve around a “developmental ladder” metaphor (Fischer, Yan, &

Stewart, 2003), whereby second language learners are metaphorically seen as traversing the distance from the relatively fixed, homogeneous mental competence of their first language to a target language competence through a series of steps or stages. The journey is made manifest through learners' production of an "interlanguage" (Selinker, 1972). The variable production evident in interlanguage ultimately gives way to target language structures that are stable over time and place, although they may be deployed differently, due to style shifting (Tarone, 1979). In this view, structures are enduringly real, object-like, truly out there in the world and also in our heads. Thus, theorists in this tradition write about linguistic structures being acquired from input and being assimilated as elements of an internal mental grammar. Traditionally, researchers have also assumed that it was possible to adopt a bifurcated research agenda, focusing on the nature of the SLA process or, alternatively, focusing on learners' differential success while engaging in the process of acquiring another language.

Shifting the Metaphor

Of course, no single researcher may subscribe to all the assumptions underlying this traditional ladder metaphor, and some of the assumptions have been abandoned as the field has evolved. Nevertheless, the metaphor of a developmental ladder has been the dominant view since the inception of the field. These days, C/CT has the potential to radically shift the metaphor under which SLA research has been conducted, from that of developmental ladder to one where development is seen as a complex process of dynamic construction within multiple ranges in multiple directions (Fischer, Yan, & Stewart, 2003), more of a web than a ladder.

Accompanying the newer metaphor is the view that language is not fixed, but is rather a dynamic system. Language evolves, changes, and is learned in the dynamics of language use between and among individuals. As a language is used, it grows and organizes itself from the bottom up in an organic way, as do other complex systems. Out of interaction in local communities, certain variegated stabilities of structure emerge—as with the flocking birds, complexity emerges at a higher level. The new level of complexity in the community is dependent upon what preceded it—its initial conditions. In this way, each new level is historically contingent, dependent on what has come before.

A complexity-inspired view of language also rejects the notion of language as something that is taken in—a static commodity that one acquires and therefore possesses (Larsen-Freeman, 2002). Instead, language is seen to be as much a process as a product, something in which one participates (Sfard, 1998). Because language is a dynamic system, continuously changing, its potential is always being developed, and it is never fully realized. This applies to the language of a speech community as well as to an interlanguage.

Although it is never static, a certain level of stability can be achieved in a complex system, where change is gradual. At other unpredictable times, the behavior of the system becomes highly unstable with the system changing rapidly from one state to another. It is especially when the behavior of a system is unstable that the organism is free to explore new behaviors in response to task demands. Indeed, it is the flexibility to discover new solutions that is the source of novel forms (Thelen, 1995). However, the system may self-organize with respect to one area of language only. Presumably there are oscillating cycles of lesser and greater order going on elsewhere in the system (Larsen-Freeman, 1997), and in the case of learner language, extended periods where alternative forms, with roughly the same meaning, exist side by side. These extended periods are often due to the strong influence of the native language, to which learners have already made a neural commitment.

Language Users/Learners

Moving now from the language system to language users and learners, it is said that as speakers interact, they “soft-assemble” (Thelen & Smith, 1994) their language resources. They cobble together existing ones and create new ones to deal with the communicative pressures at hand. The assembly is said to be “soft” because the elements being assembled, as well as the specific ways in which they are assembled, can change at any point during the interaction. Thus, soft-assembly refers to processes involving the articulation of multiple components of a system, where “each action is a response to the variable features of the particular task” (Thelen & Smith, 1994, p. 64). Ultimately, “It is the multiple integrations of many component processes in many different tasks that leads to a system that is flexible, inventive, and exquisitely adaptive” (Smith & Breazeal, 2007, p. 67).

The soft-assembled patterns that arise from interaction are the products of dynamic adaptation to a specific context (Tucker & Hirsh-Pasek, 1993). The adaptation to a context includes the process of coadaptation in which each individual in an interaction imitatively adapts to the language of another. This points to the importance of the social embeddedness of human cognition. In addition, the view that language is social stems from the fact that it is used for social action within a context of language use, where pressures and affordances, learners’ identities, goals, and affective states will all have a profound effect on language performance (van Lier, 2004). Learners do not reproduce their linguistic world—they actively transform it.

This is true for the language use of both proficient speakers and language learners. The patterns are “created and dissolved as tasks and environments change” (Thelen & Bates, 2003, p. 381). Some patterns are preferred; others are more ephemeral. In fact, we would be better off using the term “second language development” rather than “second language acquisition” in that learners have “the capacity to create their own patterns with meanings and uses (morphogenesis) and to expand the meaning potential of a given language, not just to internalize a ready-made system” (Larsen-Freeman & Cameron, 2008, p. 116). Language acquisition is not a matter of conformity to uniformity. Thus, developmental change seems “not so much the stage-like progression of new accomplishments as the waxing and waning of patterns, some stable and adaptive and others fleeting and seen only under special conditions” (Thelen & Bates, 2003, p. 380).

Nativists believe that the input to children acquiring their native language underdetermines the complexity of language, and they therefore assume that the complexity needs to be prespecified in the form of a universal grammar, an innate faculty with which all humans are endowed. However, from the perspective of C/CT, first and second language development can be seen to stem from the emergence of new forms in a complex system. What is striking from a complex systems view is that the language learning child or adult produces language that is richer or more complex than the language addressed to her or him (van Geert, 2003, p. 659). This is a commonly observed property of all complex systems, in which complexity emerges not from input to the system nor from an innate blueprint, but rather from the creation of order, internal both to the language learner and, at another level, to the external community through social processes such as in the development of pidgins.

Usage-Based Emergentism

Stable language-using patterns emerge from repeated soft-assemblies (Larsen-Freeman & Cameron, 2008). Usage leads to these becoming entrenched in the speaker’s mind and to them being taken up by members of the speech community. Thus, a usage-based (e.g.,

Tomasello, 2003) or emergentist (Ellis & Larsen-Freeman, 2006) view of language acquisition aligns well with C/CT. According to this view, language has the shape that it does because of the way that it is used, not because of an innate bio-program or internal mental organ. As for acquisition, it is the frequency of patterns in language use that promotes learning. The patterns can be characterized as Zipfian, where certain prototypical forms occur with far greater frequency than do others, recruiting learner attention and thus aiding the implicit language acquisition process. Such patterns exist at every level of scale from phonemes to morphemes, lexical items, phrases, idioms, non-canonical collocations, grammar constructions, conversational structures, and so forth. However, instead of being composed of rule-governed linguistic units, which may have no psychological reality for learners, the patterns may be “pastiche of various kinds of item-based constructions” (Tomasello, 2000, p. 76).

As learners revisit the same territory again and again, they perceive and begin to recognize patterns at these levels of scale; they register them in memory. With subsequent encounters, the pattern is strengthened in memory (in neural networks we speak of the connection weights being increased). However, it is not merely numerical superiority that privileges certain patterns above others and leads to their earlier appearance in learners' production. For one thing, there is the influence of the L1, which acts as a filter on perception. For another there is the contingency factor. Certain forms are uniquely associated with a meaning or with a use. They will be easier for a learner to notice and to acquire than structures in the language that are polysemous. Another factor influencing which forms get noticed and used is the status of the individual who uses the form. Presumably the language resources of individuals with higher status will be more influential than those of lower status individuals. Another factor is the affective attachment learners have to certain patterns over others (Todeva, 2009).

Because each interaction is unique, there is a great deal of variation at one time in learners' performances and clear instability over time. Variation and fluctuation are important characteristics of dynamic systems (Thelen & Smith, 1994; van Geert & van Dijk, 2002) and should not be dismissed as measurement error. The fluctuation and variability is in part because language learners dynamically adapt their language resources to the context, and the context is always changing. Thus, there is a dynamic interplay between a person's abilities and context affordances (van Geert & Steenbeek, 2005). While it is possible to separate context and person for the purpose of analysis, such separation requires the untenable assumption that the two are independent (van Geert & Steenbeek, 2005). Individual developmental paths, then, each with all its variation, may be quite different one from another, even though in a “grand sweep” view these developmental paths appear quite similar (de Bot, Lowie, & Verspoor, 2007). One consequence of this is that generalizations about learning are elusive and not likely to hold regardless of the individual involved or of the context (e.g., tutored versus untutored). This is all the more so in multilingual situations where the routes of learning naturally show still greater diversity (Jessner, 2008).

Individual Differences

Generalizations about learners are not likely to hold either. Individual differences naturally follow from the fact that individuals tend to actively select and manipulate the contexts in which they function (van Geert & Steenbeek, 2005). In fact, it could be said that individuals not only determine what aspects of the outside world are relevant to them, but they actively construct a world around themselves and are constantly altering it (Lewontin, 2000). A C/CT view sees learners' language resources as resulting from use, recognizing

the centrality of variation and the intentionality of learners in choosing the forms that they do. It also recognizes that individual difference factors, such as motivation, do not function as a state but rather as a dynamic process, characterized by motivational ebbs and flows. Such a perspective is congruent with recent conceptualizations of motivation in SLA, in which motivation is seen as operating under the influence of various interacting elements producing continuous change within the system (Dörnyei, 2009).

Implications for Research Methods

How the variability and specific adaptations of soft-assembled “make-do” solutions at one time lead to the instability and stability of development over time is of course the central concern of SLA research and will remain so. What are needed are individual microdevelopmental studies that seek to understand the mechanisms by which learners “forgo old ways of behaving and adapt new ones” (Thelen & Corbetta, 2002, p. 60). Microdevelopment studies require much denser data collection intervals than what is typical in SLA research.

Newer approaches to the study of complex dynamic systems involve computer modeling. While such models are reductions in and of themselves, they have the decided advantage of allowing the investigation of the dynamic interactions of these factors in language learning, processing, and use while accelerating the process in a simulated fashion (Ellis with Larsen-Freeman, 2009).

In addition to modeling, van Gelder and Port (1995) offer dynamical description as an approach to the study of dynamical systems. Dynamical description “provides a general conceptual apparatus for understanding the way systems—including, in particular, non-linear systems—change over time” (van Gelder & Port, 1995, p. 17).

It is clear, though, that cross-sectional research by itself is not adequate to capturing the dynamism of the process. While cross-sectional research gives researchers a picture of the “grand sweep of development” where global structure and similarities across participants can be seen at one point in time, it obscures what is happening at the level of the individual over time. Therefore, as a complement to cross-sectional research, “a view from below” is needed, where the “messy little details” lie (de Bot, Lowie, & Verspoor, 2007, p. 19). It is by looking at these that we see that behavior is variable and context dependent. Further, “it is very well possible that if we look close enough that the general developmental stages individuals go through are much less similar than we have assumed so far” (de Bot, Lowie, & Verspoor, 2005, p. 24).

Conclusion

To underscore the impact of C/CT on SLA, what is on offer here is not a piecemeal weighing of the traditional assumptions, but a call for a wholesale perspective shift, from a developmental ladder to an emergentist web perspective, one that sees linguistic signs not as “autonomous objects of any kind, either social or psychological,” but as “contextualized products of the integration of various activities by [particular] individuals in particular communicative situations. It logically follows that they are continually created to meet new needs and circumstances” (Toolan, 2003, p. 125). The dynamism of language and learning central to this position frames questions concerning SLA in a different light from traditional views.

Language learning is not seen to be a linear, additive process, but a nonlinear, iterative one (de Bot, Lowie, & Verspoor, 2007), which is context-dependent and variable. For this reason, what generalizations exist at the group level often fail at the individual level. In

fact, different learners may develop different language resources even when the ambient language is similar (Mohan, 1992). "The ideas of 'soft-assembly' and historical contingency offer a way of conceptualizing both the global and universal changes in development as well as the local, variable, and individual pathways" (Thelen & Bates, 2003, p. 382).

With C/CT not only do we get a more variegated portrayal of a learner's language resources, but we also get a different, more emic, account of its development. Learning is not the taking in of linguistic forms by learners but the constant adaptation of their language resources in the service of meaning making in response to the affordances that emerge in the communicative situation. Learning does not add new forms to the system; it changes the system.

Chapelle, Carol A.

JOAN JAMIESON

Carol A. Chapelle (1955–) is distinguished professor of liberal arts and sciences at Iowa State University, where she has taught and conducted in research applied linguistics since 1985. Her research and teaching is aimed at developing productive links between knowledge in applied linguistics and educational practices, particularly with respect to the use of technology for language learning and assessment. Her limited success as a learner of Russian in high school and college may have prompted her interest in the challenges faced by the adult language learner and their practical consequences for teaching—an interest that has sustained her teaching and research in computer-assisted language learning and language assessment.

Chapelle graduated from Michigan State University with a bachelor's degree in linguistics. She then attended the University of Illinois at Urbana-Champaign, completing her master's degree in teaching English as a second language in 1979 and PhD in a crossdisciplinary program on second language acquisition and teacher education in 1983. The timing of her graduate work coincided with the development and use of computer-assisted instruction for second language teaching at the University of Illinois, where a large computer-assisted instruction system (PLATO) had been in place since the 1960s. By the late 1970s many hours of instruction were being delivered by the system for students of English as a second language and students studying many other languages. Observation of ESL students' use of these materials was revealing for Chapelle: the intensive individual interaction and feedback learners received through the use of PLATO far exceeded what they got in a classroom, but there was a need to understand the effects and potential value of this new form of interaction. She and Jamieson conducted three studies that drew upon data collected as students interacted with the ESL materials on PLATO (Chapelle & Jamieson, 1981; Chapelle & Jamieson, 1986; Jamieson & Chapelle, 1987). The positive reception of this work in addition to her conviction that improvements were needed in second language pedagogy fueled her work on technology and second language learning over the following years.

Stemming from the need to understand the effects of computer-assisted language in order to design better materials for learners, Chapelle's work in this area has explored two fundamental issues: (a) the connection between the design of computer-assisted language learning tasks and research on second language acquisition (e.g., Chapelle, 2005, 2009) and (b) research methods that can help to illuminate the learning that takes place in computer-assisted language learning (e.g., Chapelle, 1990, 1997). Chapelle advocated the use of research designs which examine design features and computer-learner interactions rather than comparing CALL to classroom instruction, which she believed were not sufficiently nuanced to reveal insights relevant to teachers and materials designers, although her paper on the evaluation of innovations suggests a role for such research in communicating with some audiences (Chapelle, 2007).

Her work in this area over three decades demonstrates that technologies for language learning are not a monolithic solution to learners' needs but rather a complex research project in which issues such as learning needs, accessibility of materials, assessment, research methodology, linguistic analysis and theoretical bases of acquisition are all important

issues. All are worthy of careful analysis and exploration, and her books, articles and presentations take up these topics in great detail. Two of her books have been particularly influential in this area: *Computer Applications in Second Language Acquisition* (2001) and *English Language Learning and Technology* (2003).

Stemming from the research methodological strand of her work on technology is another of Chapelle's research areas—language assessment. The basis for claims made in most empirical research comes from some form of language assessment, and therefore the interpretations made on the basis of assessment results need to be valid. Researchers and teachers regularly make interpretations about students' learning, their abilities, and their performance. The validity of the interpretations and uses of assessment results is the most critical piece of any research on technology and language learning, but how can one demonstrate validity? An exploration of a response to this basic question has resulted in many papers and books that investigate the validity of interpretations from specific tests (e.g., Chapelle & Abraham, 1990; Chapelle, Jamieson, & Hegelheimer, 2003) and discuss the issues of validity and validation as they have evolved over the past 25 years (e.g., Chapelle, 1998, 1999; Chapelle, Enright, & Jamieson, 2010). Key works in this area are a 1998 paper entitled "Construct Definition and Validity Inquiry in SLA Research," which lays out three distinct approaches to defining the constructs used as the basis for test development and validation and the 2008 explanation of "The TOEFL Validity Argument." This line of research has also provided a means of addressing substantive issues in the use of technology for language assessment, which have been explored in her books, but most centrally in *Assessing Language Through Computer Technology* (Chapelle & Douglas, 2006).

Due to social factors beyond applied linguistics, the practical uses of computer technology in language learning and language assessment have expanded dramatically over the past thirty years. As a consequence, Chapelle's work has been useful for a growing field with many new applied linguists wishing to engage with the current issues. In response to this need, the applied linguistics program at Iowa State University developed a doctoral program to provide the intellectual space for cultivating interest and harvesting knowledge of professionals to expand their capabilities as language teachers and learners through the use of computer technology. Like the University of Illinois at Urbana-Champaign, where Chapelle's interests were piqued by the PLATO project, Iowa State University of Science and Technology creates an environment for exploration and use of computer technology in applied linguistics. The Atanasoff-Berry Computer, the first electronic digital computer, was built by John Vincent Atanasoff and Clifford Berry at Iowa State University during 1937–42 (JVA Initiative, 2005).

It is a university where a fruitful research–practice interface is viewed as the key criterion for success, and therefore provides a hospitable environment for Chapelle's praxis-oriented research program. She makes accessible knowledge about applied linguistics to those engaged in practical work in applied linguistics through publications, professional service, and serving on advisory boards for projects in language assessment. She has served as editor of *TESOL Quarterly* (1998–2004) and president of the American Association for Applied Linguistics (2006–7); she is the coeditor of the *Cambridge Series in Applied Linguistics* (with S. Hunston). Her book, *ESOL Tests and Testing: A Resource for Teachers and Program Administrators* (Stoynoff & Chapelle, 2005), has been on the TESOL best seller list. Her book, *Tips for Teaching With CALL: Practical Approaches to Computer-Assisted Language Learning* (Chapelle & Jamieson, 2008), is widely used by teachers beginning to use computer-assisted language learning. The commitment to make accessible the knowledge in applied linguistics to a broad audience is at the basis of her motivation to develop the present *Encyclopedia of Applied Linguistics*.

Child Pragmatic Development

ASTA CEKAITE

Language is a tool that children and adults use to act in and explore the social world; to create, develop, and sustain social relationships; and to engage with others in culturally meaningful activities. Thus, pragmatic development involves children's acquisition of communicative competences, that is, learning how to use language, to communicate and understand others appropriately and effectively in a widening range of social contexts and activities while assuming increasingly complex social roles (Hymes, 1972). In contrast to children's development of grammar and syntax, consistently shown to be largely completed by the age of 5 years, children's sophisticated mastery of varied conversational skills is a long-term process. Basic pragmatic skills emerge at quite an early age, but are refined and developed throughout preadolescence and adolescence, over time allowing the child to engage in a constantly broadening range of social activities, and to become a full-fledged member of the culture and society. Indeed, children's acquisition of communicative competence has crucial social and educational implications. Conversational skills play a major role in a child's access to interactions with peers and in forging peer-group relations in the first and second language. Such skills are important in adult-child relations, qualifying children as interactionally competent students in educational settings, and play a significant role in shaping children's written literacy skills.

Research Perspectives on Pragmatic Development

The study of child pragmatic development is a heterogeneous field that brings together linguistic pragmatics and child development, and encompasses different traditions and theoretical perspectives on language and social interaction: socioculturally informed research such as developmental pragmatics (Ervin-Tripp, Guo, & Lampert, 1990; Ninio & Snow, 1996; Blum-Kulka & Snow, 2002), sociolinguistics (Kyratzis & Guo, 2001), language socialization (Ochs & Shieffelin, 1984), and developmentally informed approaches to child language acquisition (Berman & Slobin, 1994). Topics studied within the field of children's pragmatic development in their first language focus on a broad range of distinct but inextricably related aspects of communicative competence: the emergence and development of verbal communicative acts (i.e., speech acts) in young children; the development of conversational skills; children's growing sensitivity to the social parameters of talk; and children's acquisition of extended discourse genres such as narratives, explanations, definitions, and so forth.

Though all the above-mentioned traditions agree that children's active participation in interactions with adults is a major driving force behind children's acquisition of communicative competence, they differ in their interests and methodological approaches. Developmental studies track the fundamental developmental process in the child's construction of pragmatic abilities. They map the universal route and rate of children's communicative development cross-culturally and across ages, grounding their analysis largely on experimentally elicited or semi-elicited data, that is, children's performance in controlled communicative tasks (Hickmann, 2003). Socioculturally informed studies on

2 CHILD PRAGMATIC DEVELOPMENT

pragmatic development examine the emergence of communicative skills longitudinally, on the basis of communicative practices in children's everyday interactions with adults and peers. Emphasizing the socially and culturally sensitive nature of conversational norms, such studies examine how everyday interactions serve as a culturally bounded foundation for children's learning and practicing of appropriate language use (Shieffelin & Ochs, 1986; Blum-Kulka, 1997).

Conversational Sites for Learning

In child pragmatics, adult-child and children's peer interactions are viewed as distinct interactional and developmental sites: these interactions afford different participant roles, communicative genres, and various degrees of conversational assistance. Adults generally support children's conversational participation by providing a model and scaffolding children's competent and equal conversational performance. Peer interactions, on the other hand, reveal children's pragmatic abilities in unaided conversational situations. Furthermore, peer talk actively contributes to children's pragmatic development: the peer discourse has its own specific gains, providing a training ground for children's conversational skills, genres, and roles unavailable to children in adult-child conversations, which are asymmetric with respect to social knowledge and power (Blum-Kulka, Huch-Taglicht, & Avni, 2004).

The Emergence and Development of Pragmatic Skills

The Emergence of Speech Acts in Young Children

Studies investigating the acquisition of verbal communicative acts (speech acts) by children have traced how very young children, starting from the preverbal stage, use linguistic means to perform social actions and examine the pragmatic goals they achieve. Notably, even when toddlers use one-word utterances, they are able to make requests for action and information and to produce statements, responses, and acknowledgments, combining these utterances with nonverbal means. For instance, the first verbal requests are designed as a combination of gestures and the name of the object requested, words such as "more," "want," and "gimme" (Ervin-Tripp et al., 1990). By the age of 2.5 years, children deploy a wide repertoire of communicative acts that gradually become more sophisticated and refined. Over time, children learn the lexicocommunicative and pragmatic means that enable full verbal and situationally sensitive realization of previously acquired communicative intents such as justifications, promises, prohibitions, challenges, apologies, explanations, refusals, and disagreements (Wells, 1985; Ninio & Snow, 1996).

Children's Conversational Skills

Children's communicative use of language allows them to respond to and to solicit further speech, thus organizing social interaction as adjacent responsive and reactive verbal actions that serve as the building blocks of conversation and intersubjectivity. Studies of children's conversations examine a complex combination of skills: children's mastery of turn-taking procedures, initiation and development of relevant topics, and ability to recognize and repair breakdowns in mutual understanding.

Turn taking concerns the ability to organize verbal interaction by taking turns, that is, by selecting an appropriate place for one's verbal contribution in conversation. Turn-taking procedures are situationally and culturally sensitive, varying depending on participation frameworks (dyadic or multiparty), activities, and social settings (de Leon, 1998). In the West, where adults treat children as conversational partners from birth, rudimentary

turn-taking procedures begin to develop long before children's linguistic productions do (Trevvarthen, 1979). In peer groups, children organize social interactions by conforming to turn-taking procedures typically by the age of 3 years, although the gaps between their turns are longer than in adult conversation (Ervin-Tripp, 1979). Multiparty encounters (e.g., family dinner conversations) constitute complex interactional situations for young children, who (still) experience difficulties with the precise timing of their self-selections (Blum-Kulka & Snow, 2002). Similarly, institutional procedures of turn taking in educational settings are the target of extensive pragmatic socialization in elementary schooling (Cekaite, 2007).

Turn taking is not an isolated conversational ability: sustaining and developing topically coherent conversational episodes requires the ability to select turns with contributions that manifest topic relatedness, that is, that respond to and add novel information to the topic at hand, thereby facilitating further development of the topic and conversation. In interactions with young children, adults tend to assume the bulk of the conversational responsibilities for topic development. They ask questions, initiate topics, expand and clarify unclear utterances, and are able to sustain conversational episodes with 2-year-olds. In children's peer conversations, topical coherence and contingent responses are recurrently achieved through varied means of repetition, sound, and verbal play. Communicative uses of repetitions and partial recyclings are documented across a broad age range, from 2-year-olds', preschoolers' (McTear, 1985), and preadolescents' peer interactions (Cekaite & Aronsson, 2004), revealing children's sophisticated lexical, syntactic, and prosodic analysis of and responsivity to previous talk. Indeed, efficient use of (partial) repetitions is one of the normative prerequisites for competent participation and acceptance in the communicative practices (arguments, disputes, play) of the peer group (Goodwin, 1990).

Children's repertoires for maintaining topical coherence develop to include formally and semantically diverse means, starting as early as 2 years of age (McTear, 1985). Achieving adult-like conversational coherence, however, has a long developmental trajectory in peer talk. Children continue to improve the topical relatedness of their conversations throughout adolescence, 10–11-year-olds still producing factually unrelated turns in their conversations (Dorval & Eckerman, 1984).

Smooth running of the conversation depends on the participants' abilities to recognize, locate, and repair misunderstandings and conversational breakdowns (Schegloff, Jefferson, & Sacks 1977). In Western contexts, adults' requests for repairs and clarifications are tuned to children's verbal skills, starting at around 1.5–2 years of age, when children's talk increases in both comprehensibility and the richness of lexicosemantic features. Children's efforts to repair conversational breakdown are documented before 3 years of age. While initially children tend to address problems of understanding by simply repeating problematic turns, older children (3-year-olds) exhibit an increased repertoire of remedial resources, deploying and answering requests for clarification that target specific problematic features of talk, and revising their utterances accordingly (Ninio & Snow, 1996). Also in peer interactions, children (between 4 and 6 years) manifest their growing concern with the smooth running of interaction and their abilities to remedy problems of understanding (McTear, 1985).

Repair skills are at the heart of children's developing understanding of the other's perspective. There appears to be cross-cultural variation in repair procedures concerning the speaker's and hearer's responsibilities for securing mutual understanding that conforms to the larger set of rules regulating interaction. In Western middle-class contexts, adults' repair initiations serve multiple functions, both as enhancing mutual understanding and as implicit socializing procedures concerning the pragmatics of conversation. Given that the primary responsibility for clarity of communication rests with the speaker, the child-speaker is expected to provide relevant background information and consistently monitor

the comprehensibility of his or her talk. In contrast, studies from non-Western contexts have shown different repair practices. For instance, in Japan children are socialized into “intent listenership”: because the responsibility for mutual understanding is attributed to the listener, children are expected to develop and deploy interpretative skills and to actively signal (non)comprehension (Clancy, 1986).

Politeness and Social Parameters of Language Use

Children’s emerging sensitivity to the social parameters of language use constitutes an area of pragmatic research that examines how and when children learn to be polite, to tune in and modify their language depending on the social context and role relations with the addressee, as well as how to master various speech registers and styles.

Politeness markers are part of children’s precocious pragmatic skills. In Western contexts, when children reach the age of 2.6–3 years, they typically vary the linguistic form of their requests according to the status and age of the addressee. Children exhibit awareness of the desirability of using indirect request forms with addressees whose social status and age are higher than their own (adults and older children/siblings), whereas when speaking with their peers, children deploy unmitigated imperatives and blunt statements. School-age children (7- to 8-year-olds) clearly extend their pragmatic repertoires: they utilize formally and semantically diverse means in the realization of requests as well as understand and design indirect requests and hints that take into account obstacles in the addressee’s situation (Ervin-Tripp et al., 1990).

Children’s peer group activities present an ideal site for observing and documenting children’s mastery and acquisition of social registers. In pretend play, for instance, children index and sustain in-character roles using a range of linguistic resources. Indeed, play serves as a major site for conversational development, providing children with opportunities for using and perfecting skills in registers that are typically associated with high status, and that are unavailable for children’s use in supportive, yet asymmetric, adult–child interactions. Children as young as 4 years of age engage in script-based play—playing family, teacher–student, or doctor–patient relationships—vary their use of language styles and registers, exhibiting sensitivity to status and social and gender roles (Andersen, 1990). Preschool children, boys and girls, master gendered language styles, using them as a repertoire of speech strategies to achieve particular interactional goals. Instead of relying on the so-called universal feminine language style, which is associated with mitigation and consensus seeking, girls adjust and manipulate their language according to participant constellations, using assertive and unmitigated speech (generally viewed as a masculine assertive and controlling speech style) when playing in mixed-gender groups (Kyratzis & Guo, 2001). While young children rely largely on register-relevant prosodic resources, in school-age children interactions and different social roles are marked and sustained collaboratively through register-relevant lexical means (Hoyle, 1998). Over time, varying language registers and styles are perfected and deployed instrumentally in preadolescents’ and adolescents’ identity work as resources marking their affinity to class, ethnicity, gender categories, or youth culture (Rampton, 1995).

In multilingual children, sensitivity to language choice emerges before the age of three, when children start accommodating their language choice to the addressee’s language preference (Fantini, 1985). Pragmatic functions of language alternation develop throughout school age, where children refine skills concerning how to use contrasting languages for managing social relations—for instance, deploying code switching as a power-wielding device (Jørgensen, 1998).

Extended Discourse Genres

Children's acquisition of extended discourse genres—narratives, explanations—is a relatively well-charted area of children's pragmatic development. In narratives, temporally distant events are described in a way that clarifies the causal relations between them. In contrast to talk, which is embedded within the here-and-now activity, when engaged in storytelling the child cannot rely on the hearer sharing experiences of the same event and must adhere to the pragmatic requirements of adjusting to the listener's knowledge and point of view. As sustained and decontextualized forms of talk, narratives require the structuring of information in linguistically and cognitively coherent and explicit ways, and involve basic skills of importance to school-related spoken and written literacy.

Studies on children's narratives follow two distinct research traditions. Socioculturally informed research investigates children's naturally occurring narratives and their narrative socialization in everyday discursive events. Thus, rudimentary narratives—children's attempts to converse about remote topics and non-present people and things—are identified very early, before the age of 2. In everyday conversations, narratives are collaboratively accomplished, and adults scaffold children's structured, audience-sensitive presentation of narrative information. By monitoring the audience for comprehension, assessments, and responses, children learn to organize narratives, choose tellable topics, and adopt appropriate affective and moral stances, thus adapting to cultural criteria for successful narrative performance (Blum-Kulka, 1997).

Developmental studies map the universal route of children's narrative development cross-culturally and across ages, assessing the well-formedness of children's autonomous, adult-unsupported narrative performance. Using highly constrained elicited narratives—asking children from different age groups and different languages to narrate a sequence of events in a wordless picture book—such studies map the general progression in the development of narrative structures and cohesion, including the development of linguistic forms for encoding the functions of temporality, causality, person, and spatial reference (Berman & Slobin, 1994).

Other forms of extended discourse that are considered part of a literate or academic register—explanations, arguments—are explored as recurrent features of peer talk and play (Aukrust, 2004). In the argumentative discourse between peers, young children display well-formed and convincing arguments, which they use to make their points (Zadunaisky-Erich & Blum-Kulka, 2010). Peer talk thus incorporates both child-unique discursive strategies and strategies that echo discursive conventions from the adult culture, enabling the refinement of both.

Conclusions

Children's pragmatic competence—their knowledge of how to configure a range of communicative resources in specific discursive practices—is developed and refined through participation in family, peer, and educational interactions, which serve as a means and motivation for skillful and strategic language use. By investigating both universal and culture-specific features of children's interactional skills, studies on pragmatic development seek to describe and detail how children learn to use language as an efficient tool for social action.

Christian, Donna

CAROLYN TEMPLE ADGER, DORRY KENYON,
JOY KREEFT PEYTON, AND NANCY RHODES

Donna Christian (1949–) is among the foremost authorities in the United States on language education and language in education. She began her academic career in mathematics, completing an undergraduate degree at St. Lawrence University with high honors, and went on to study applied linguistics and French at Georgetown University. As one of the first students in Georgetown's sociolinguistics program (PhD, 1978), Christian conducted dissertation research on the dialect of the Appalachian region. *Appalachian Speech* (1976), which she wrote with Walt Wolfram, still stands as the seminal source on this dialect. Christian's collection of American English dialect recordings is available in The Library of Congress American Memory series (<http://memory.loc.gov/ammem/collections/linguistics>). This collection of interviews and other speech recordings, primarily from dialect research and oral history projects, provides a centralized source of North American dialect samples, preserving linguistic resources that might otherwise be lost. Christian taught linguistics and education courses for George Mason University, Georgetown University, the George Washington University, the University of California-Santa Cruz, and the University of Virginia. In 1979, she received a Fulbright Senior Lecturer award in linguistics and taught for two years at Adam Mickiewicz University in Poznań, Poland.

Donna Christian is well known for her leadership at the Center for Applied Linguistics (CAL). Beginning there in 1974 as a research assistant, while a graduate student, Christian rose to become director of the research division, secretary of the corporation, and vice president. In 1994, she was named president. In that capacity, she led CAL's efforts to recognize and respond wisely to language and language learning issues in the United States and beyond through research on language and language learning; technical assistance to national, state, and local governments; and professional development for educators on language learning. Christian led the organization through a period of growth to articulate a mission and a vision, refresh the organizational structure and procedures, and enhance its reputation as a leader across the subdomains of applied linguistics. She encouraged innovation in applying research to social challenges, such as supporting language immersion, heritage language development, annual English-language proficiency testing for adults and K-12 students, and content area testing for students with low levels of English proficiency.

Christian's own contributions to the field of applied linguistics include research and publication in aspects of K-12 education where research had been sparse. Two areas of particular focus are vernacular dialects in education settings and dual-language education programs. In addition to her research on Appalachian English, her research on Ozark English, Native American English, and Vietnamese English is part of the sociolinguistic research canon on vernacular English. With Walt Wolfram, she wrote *Dialects and Education: Issues and Answers* (1989), which addressed urgent questions from educators about language variation. That volume was revised as *Dialects in Schools and Communities* (2007) (with Walt Wolfram and Carolyn Adger) for use in teacher preparation and educational services. In the wake of the Ebonics controversy of 1996, Christian organized a meeting of concerned scholars in linguistics and education, which led to publication of *Making the Connection:*

Language and Academic Achievement among African American Students (1999) (with Carolyn Adger and Orlando Taylor).

As two-way immersion programs (a form of dual-language education) gained numbers in the 1980s and 1990s, Donna Christian led collaboration on documenting practice and defining program models (Christian, Montone, Lindholm, & Carranza, 1997). *Guiding Principles for Dual Language Education* (2007) (developed with Elizabeth Howard, Julie Sugarman, Kathryn Lindholm-Leary, and David Rogers), which describes the approach, program models, and the research base of two-way immersion, is considered a fundamental reference and guide for two-way program design and evaluation.

Christian's contributions to the field extend beyond these areas of particular interest and expertise. Her publications on language learning have addressed policy, programs, and instructional practice in foreign language learning in the United States, English language learning, and heritage language programs. She was one of the first to see the importance of collaboration across the fields of foreign language, English as a second language, and content area learning; and she was instrumental in helping the profession of language educators see the benefits of integrating language and content area teaching and learning, starting in the early grades.

Donna Christian's leadership on the national scene has included appearing as an expert witness in hearings on Capitol Hill and as a participant, moderator, and discussant in numerous panels on language policy. She has served on the boards of directors of the International Research Foundation for English Language Education (TIRF) and the Joint National Committee for Languages; on the advisory board of the Hispanic Family Literacy Institute (National Center for Family Literacy); and on the editorial boards of the *Heritage Language Journal*, the *International Journal of Bilingual Education and Bilingualism*, *College ESL*, and *American Speech*. For the Linguistic Society of America, she served on the Audit Committee and on the Committee on Language in the School Curriculum. For many years, Christian has been an *ex officio* member of the Executive Committee of the American Association for Applied Linguistics.

The field of applied linguistics has grown and benefited from Donna Christian's vision and leadership in using the research base to create a society in which language and culture are valued.

Citizenship Education

MICHAEL BYRAM

Citizenship education, whether under this label or under some other, such as “civics,” “éducation civique” or “politische Bildung,” has a long history (Heater, 2004); the field is also attracting increasing contemporary interest and, therefore, a source of growing academic literature. The recent appearance of a *Handbook of Education for Citizenship and Democracy* (Arthur, Davies, & Hahn, 2008) might indicate that there is a settled body of knowledge to which the book provides guidance, but the tendency to polemic in some of the articles indicates that this is not the case. The appearance of collections of essays too (e.g., Stevenson, 2001; McDonough and Feinberg, 2003) in which there is frequent reference to “dilemmas” or to new theories and terms, is another indicator of flux. A third stream, of comparative studies, includes collections of articles describing citizenship education in a range of countries (Lee, Grossman, Kennedy, & Fairbrother, 2004; Grossman, Lee, & Kennedy, 2008; Zajda, Daun, & Saha, 2009), sometimes with minimal attempts to establish a comprehensive perspective (Jackson, 2002; Schweisfurth, Davies, & Harber, 2002), and a large-scale survey of “civic education” in 28 countries (see IEA Civic Education Study, <http://www.terpconnect.umd.edu/~jtpurta/>) in 1999 and 2000. This was renewed and repeated 10 years later with a significant change of title from “Civic Education Study” to “Civic and Citizenship Education Study” (see IEA International Civic and Citizenship Education Study, <http://iccs.acer.edu.au/>) and an increased number of participant countries, indicating perhaps higher international interest in the issues.

In the midst of this academic analysis of constantly changing complexity, it is the authors of the kind of handbook which helps teachers to plan, teach, and possibly assess courses and activities in citizenship education who dare to be firm in their recommendations. The introduction of obligatory citizenship education or the development of new curricular directions encourages publishing to fill immediate needs, specific to local circumstances. If the implementation of citizenship education is to permeate the curriculum, there are books for teachers which deal with citizenship education as a “whole school approach” (Turner & Baker, 2000a), but there is also an approach that includes citizenship education in each subject (Turner & Baker, 2000b). If, as a third option, the approach is to have a separate subject, then books are available for teachers with a qualification and specific responsibility for “citizenship education” (Gearon, 2009). Further, traditional publishing is complemented by Web sites produced by education authorities wanting to advise and influence teachers (e.g., <http://www.citized.info/>; <http://www.curriculum.edu.au/cce/>; <http://cspe.slss.ie/index.html>).

Concepts and Themes

In the midst of this complex field, a critical reading of work on citizenship education can be based on concepts and themes which are addressed whatever the approach. The applied linguist might use discourse analysis to throw more light on citizenship education; here we can identify some of the dominant concepts and themes.

The assumption that citizenship and democracy are necessarily associated with each other is widespread, not only in the title of the handbook referred to earlier, the first

article of which is on democracy (Crick, 2008). In Germany, a tradition of teaching established soon after the end of World War II was originally termed “politische Bildung” (“political education”), with a federal center to support it (Bundeszentrale für politische Bildung; see <http://www1.bpb.de/>), but this term has been challenged with the term “Demokratielernen” (“learning democracy”) (Himmelman, 2001; Himmelman and Lange, 2005). The challenge echoes the emphasis of the Council of Europe on “Education for Democratic Citizenship” (see <http://www.coe.int/edc>).

Yet there are other kinds of citizenship education in the past and the present. As Heater (2004, p. 152) points out, the phrase “totalitarian citizenship education” may appear to be an oxymoron but nonetheless exists in the world. Heater discusses Nazi Germany and the Soviet Union. Contemporary cases so far appear only in travel literature, for example the description of nation building in Turkmenistan around the personality cult of the president and his literary works, on which students take compulsory tests (Brummell, 2005, p. 13).

Furthermore, “democracy” is a complex concept in Western thought (see Crick, 2008), and it is a complex transplantation in other parts of the world (e.g., China, discussed by Feng, 2006), with consequences for the notion of citizenship itself and citizenship education.

“Community” is a second fundamental term, which is seldom defined, not even using Tönnies’s (1887/2002) well-known contrast with “society.” Citizenship education is presented as the relationship of the individual and his or her community, or more often “communities.” Another distinction can be made between “nationality” and identification with a group of people who “imagine” themselves to belong together as a community (Anderson, 1991) on the one hand, and on the other “citizenship,” which connotes a (usually legal) relationship of rights and duties between an individual and a state. Nation-states assume, not always justifiably, that individuals identify with an entity both as a state society and as a national community. In the most striking development of this, a relationship now exists between individuals and the European Union as a political entity, in fact made up of more than 20 member states. European citizenship is the first example of a supranational citizenship based in law, whereas an identification with a European nation scarcely exists. Other concepts of supranational citizenship, including “global” or “world” citizenship, are not legal concepts but aspirations to identification with supranational communities; the notion of cosmopolitanism, which has a long pedigree (Carter, 2001; Heater, 2004), has become the most dominant of such concepts in recent times with the idea of “cosmopolitan citizenship” (e.g., Osler & Starkey, 2005a).

The notion of “community” is also used to refer to groups of people—sometimes temporary and in flux, sometimes static and unchanging—larger and smaller than the populations of states. The use of the term to refer for example to a “global community” (Banks, 2008, pp. 61–2) is frequent, although Banks believes that of all the communities with which an individual might identify, the “nation” is most important, because nation-states offer a “background condition” for democracy and “social solidarity.” There is, nevertheless, a large and growing literature on the concept and reality of global community or global civil society (Anheier, Glasius, & Kaldor, 2004).

“Social solidarity” is a synonym of other key concepts: “inclusion,” “cohesion,” and “diversity.” Although all societies are and have always been “diverse” in some way—even if the diversity has not been recognized or has been ignored—it is the contemporary phenomena of global mobility, migration, and global communications that creates a visible and sometimes disturbing diversity in state societies. The discourse of inclusion attempts to counteract diversity and the multiplicity of communities, some of which transcend state boundaries. Citizenship education which encourages identification with nation-states is made responsible for creating cohesion. However, cultural citizenship, cultural rights, and identification with multiple communities should be acknowledged as of equal importance as political, social, and economic rights (Stevenson, 2001). There is a concern to include

groups considered marginal—for example in the Council of Europe's *White Paper on Intercultural Dialogue* (2008)—but this hides an assumption of a mainstream within a state society.

Debates about whether society can prosper with many diverse groups living side by side, or whether inclusion is crucial to success, are unfinished, and involve the question of patriotism and whether citizenship education should cultivate loyalty to country and state. Citizenship education can include explicit patriotic practices such as learning a national anthem (recently introduced into French schools) or saluting a national flag (well established in the USA and under discussion in other countries). Patriotism is in potential tension with supranational citizenship since in principle the two may make opposing demands (Carter, 2001, pp. 172–4), although in practice young people may have no problem with multiple allegiances (Mitchell & Parker, 2008).

Whatever identification is encouraged, “active citizenship” is often invoked, together with “participation.” Where the school is seen as a community, “participation” means inclusion of pupils in governance and in service. Furthermore, instead of defining schooling as preparation for later life, education policy can require activity in communities outside the school and handbooks for teachers may provide help with what for many is a new relationship for schools (Potter, 2002).

Finally, the term “citizenship education” itself needs to come under scrutiny. Its prominence is recent—though it can be traced to the 1930s as Brennan says in a book entitled *Political Education and Democracy* (1981)—and it is more dominant in Europe than elsewhere; for example, in the USA, the term “civic education” is used, and in Singapore the term “national education” betrays a patriotic approach. Alongside citizenship there are established terms including “peace education,” “global education,” “human rights education,” and “world studies.” To analyze the commonalities and differences is not possible here but would further clarify the nature of each and how each may incorporate elements of others.

Citizenship Education and Applied Linguistics

With few exceptions (e.g., Osler & Starkey, 2005b), authors on citizenship pay little attention to language, and yet the applied linguist would associate “community” with “speech community” and consider active participation in community as dependent on linguistic competence. Anderson's (1991) notion of an “imagined community” as the foundation of nation-states is based on people being literate and communicating through print. Today this can be extended to electronic media, and include speech. Furthermore, language communities exist both within and beyond national boundaries.

The significance of language teaching and learning is recognized in the testing of immigrants' knowledge of the language(s) of a country and the offer or obligation to take classes to attain a minimal competence for participation in society. Foreign-language teaching can also be a site for citizenship education (Starkey, 2005); linguistic competence has to be enriched by intercultural competence (Guilherme, 2002); and specific connections between language education and global citizenship are a new development in the debate (Birch, 2009). The commonalities in the aims of foreign-language education and citizenship education should lead to a reorientation of the former to complement the latter (Byram, 2008).

On the other hand, though there has been a renewed interest in the theory of “deliberative democracy” (e.g., Center for Deliberative Democracy; see <http://cdd.stanford.edu/>), not least under the influence of Jürgen Habermas, it is striking that whether the focus is on multilingual states or on “transnational democracy” there is no apparent awareness of the linguistic demands of “deliberation across boundaries,” which is seen as “straightforward” (Dryzek, 2002, p. 116).

Clark, John L. D.

MARTYN CLARK

John Levan Demaree Clark (1936–) has been influential in promulgating the use of direct testing methods in the assessment of speaking proficiency. These methods emphasize the elicitation of actual samples of speech in a communicative context to assess oral ability rather than relying on inference from tests of listening ability or knowledge of vocabulary and grammar. He strongly advocated the adaptation and use in regular academic contexts of the oral proficiency interview techniques developed initially by the Foreign Service Institute (FSI) of the US State Department. The work of Clark and other colleagues was instrumental in the development, professional endorsement, and dissemination of the ACTFL (American Council on the Teaching of Foreign Languages) Proficiency Guidelines and the corresponding growth of the so-called proficiency movement in foreign language teaching in the United States.

In addition to his work in the speaking testing arena, Clark was concerned with the state of the language testing field in general, suggesting broad-scope research programs and innovative assessment approaches including the use of computers long before they became common fixtures in schools. Throughout his career, he championed an intellectually rigorous approach to addressing theoretical and conceptual issues in language testing while maintaining sensitivity to and respect for real-world operational considerations as well. Many of his writings remain classics in the field, and show clarity of purpose and, on occasion, considerable wit.

Clark majored in French at Amherst College and obtained a master's degree in Romance languages at the University of North Carolina. Interested in exploring language-related areas other than the increasingly detailed study of Romance literature, he applied for and was accepted as a doctoral candidate in the Research In Instruction Program at Harvard University Graduate School of Education (HGSE). There, he worked with John B. Carroll as a senior assistant on two major language assessment projects: a parametric study of language training in the Peace Corps and a nationwide survey of the linguistic ability of undergraduate foreign language majors in their senior year. Over the course of these and other research projects at HGSE, Clark gained the keen interest in language testing that would shape his future career.

Shortly before obtaining his EdD from Harvard in 1967, Clark joined the Educational Testing Service (ETS), where he worked on a variety of test programs including the College Board Achievement Tests, Advanced Placement Tests, and the Test of English as a Foreign Language (TOEFL). At the time, the testing of speaking skills received little emphasis at ETS or in the academic language field in general, and Clark became interested in addressing this disparity. He pursued this interest by initiating the so-called "common yardstick" project together with Protase Woodford, an ETS colleague. The goal of this project was to develop, in collaboration with the American Council on the Teaching of Foreign Languages (ACTFL), a common metric for describing speaking proficiency attainments in secondary school language classes and beyond by suitably adapting the speaking proficiency descriptions and oral interview procedures that had been used at FSI and other government agencies since the 1950s. This effort was the genesis of what became the ACTFL proficiency guidelines, now widely used as a common standard for describing proficiency in foreign language education programs in the United States.

DOI: 10.1002/9781405198431.wbeal0132

Instead of indirectly estimating the presumed speaking ability of the examinee through measures of vocabulary or structural control on a written test (or through highly artificial “speaking” exercises that bear little resemblance to real-life communication), the FSI and ACTFL proficiency tests make use of a face-to-face interview aimed at determining what the speaker can functionally do with the language, beginning at a fairly simple conversational level and becoming increasingly demanding. Although seemingly a friendly informal conversation, the interview is carefully structured to continually probe and confirm that the speaker can indeed perform all of the functions in all of the domains associated with a particular proficiency level. The interview continues until the examinee is clearly no longer able to hold his or her own, at which point the interview winds down. The highest level of sustained performance demonstrated is considered to represent the examinee’s proficiency rating.

In addition to working on direct proficiency testing techniques, Clark was interested in the possibility of adding a speaking component to the TOEFL program, whose operational constraints precluded the use of face-to-face elicitation procedures. He and other ETS colleagues investigated a variety of “semi-direct” approaches, in which test stimuli are delivered by a recording or printed material or both, with the examinee’s responses recorded for later evaluation. This work (Clark & Swinton, 1979) resulted in the Test of Spoken English (TSE), which became one of the most widely used semi-direct tests of speaking ability until it was discontinued in 2010.

While advocating and promoting a rigorous conceptual basis for language testing of all types within the testing community, Clark was also keenly aware of the need to bring this information to language teaching practitioners. Toward this end, he published *Foreign Language Testing: Theory and Practice* (1972), in which he stressed the need to align test development and test selection with test purpose. He was also one of the first to highlight the important distinction between achievement testing (covering what a learner has gained from a particular course of study) and the broader notion of proficiency testing, which is concerned with the real-life communicative competencies of the learner, irrespective of any particular course of study. To describe the evolving classroom activities aimed at developing communicative use of language while at the same time operating within the lexical and structural limitations of a particular course, Clark coined the term “prochievement.” When asked on occasion how this term came into being, he would typically reply that “‘achiciency’ just didn’t seem to cut it.”

Throughout his career, Clark participated in a variety of conferences and conducted numerous workshops to introduce oral proficiency concepts and testing techniques in educational settings and testing institutions both in the United States and abroad. Under an ETS contract with the US Peace Corps, he traveled to some 19 countries to conduct face-to-face interview training and rating sessions for Peace Corps staff in these areas.

As part of a large-scale survey of college students’ understanding of global issues conducted by ETS, Clark experimented with the notion of student self-assessment of language skills through the use of what he termed “can-do” statements (Clark, 1981). Although the detailed verbal descriptions of language ability provided in the FSI, ACTFL, and other similar proficiency level scales are generally understood and can be suitably applied by trained raters, they are not as readily grasped by nonspecialists. By recasting verbal descriptions of proficiency levels as short, highly focused descriptions of particular language use tasks (e.g., “I can order a simple meal in a restaurant”), they are more easily understood by language learners without the need for formal training on the proficiency descriptors themselves. The use of “can-do” statements for student self-assessment and for teacher assessment of students has since been widely incorporated into the Common European Framework of Reference (CEFR) as well as reintroduced in an American context as interest in the CEFR process has increased in the United States.

In 1981, Clark joined the Center for Applied Linguistics (CAL) in Washington, DC as director of the Foreign Language Education Division. While at CAL, he continued to promote oral proficiency testing, overseeing development of a semi-direct, tape-mediated proficiency test of Chinese (Clark, 1986a), together with a detailed handbook for creating similar tests in other less commonly taught languages (Clark, 1986b). The operational intent of the Chinese test was to present tape-recorded questions and other spoken stimuli designed to elicit, to the extent possible, a sample of spoken language similar to that obtained from a face-to-face proficiency interview. This speech sample was recorded for later evaluation by trained raters in accordance with the levels of ability specified in the general proficiency descriptions. The tape-mediated test is not a direct substitute for the live interview, but is a reasonable alternative for situations in which face-to-face interviewing is not feasible.

Throughout this period, Clark maintained his interest in promoting research-based practice in classroom language instruction, working on projects to document teaching materials for less commonly taught language programs (Clark & Johnson, 1982). With Eleanor Jorden, he conducted research on language attrition (loss of language skills over time) on the part of students of Japanese (Clark & Jorden, 1984), and later wrote a detailed exposition of the conceptual and methodological issues involved in researching and measuring such loss (Clark, 1982).

In 1986, Clark became the dean of program evaluation, research, and testing at the Defense Language Institute Foreign Language Center (DLIFLC) in Monterey, California, where he directed a 50-person staff involved in these three areas. In the testing area, he supervised the design and development, for the more widely taught DLIFLC languages, of an improved version of the Defense Language Proficiency Test series—reading and listening proficiency tests based on FSI-type proficiency guidelines and widely used by the US Department of Defense and other federal agencies. He also supervised DLIFLC's interview-based speaking testing program, and in this capacity served in the early 1990s as chairperson of the interagency Federal Language Testing Board (FLTB). This body was charged with proposing standardized elicitation techniques and rating procedures for speaking proficiency interviewing across the major government language-training institutions, with the goal of counteracting the somewhat disparate testing styles and rating procedures that these agencies had locally and independently adopted over time.

Even though most DLIFLC testing projects and processes were not readily available to the general public, Clark continued to contribute insights and recommendations to the language-testing field at large. For example, long before computers became commonplace in the schools, he proposed a detailed research agenda for their use in language learning and testing (Clark, 1988). He strongly cautioned that computer technology should be viewed as only one part of an overall system of language instruction and assessment, conceptually including the live teacher and a number of other "delivery" mechanisms. He correspondingly urged that close study and detailed specification of the intended learning or assessment outcomes should always precede and inform the adoption of a particular technological approach.

In the early 1990s, Clark elaborated on his long-held view that language teaching and testing should not be operated as a "cottage industry" but that the field should take steps to become a fully professional discipline through greatly expanded networking, collaboration, and coordination of efforts across institutions and individuals, aided by recent major advancements in computer-based data collection and dissemination (Clark & Davidson, 1993). He argued that such an approach, if conscientiously implemented, would move the language learning and testing endeavor away from the fragmented efforts of individual groups and provide a strong and highly feasible foundation for exponential progress in both fields.

Following his retirement from DLIFLC in 1996, Clark has remained active in the language-testing arena on a consultant basis, including serving from 2006 to 2008 as chairperson of the Defense Language Testing Advisory Board (DELTAB), charged with examining and recommending improvements in the DLIFLC testing program. In 2006, John L. D. Clark was awarded the University of Cambridge Local Examinations Syndicate/International Language Testing Association (UCLES/ILTA) Lifetime Achievement Award in recognition of his numerous contributions to the field of language testing.

Classroom Research on Pragmatics

ALICIA MARTÍNEZ-FLOR

The classroom is an educational setting where two or more persons meet for a given period of time for the purposes of learning, for example, languages (van Lier, 1988). Classroom organization is essential in terms of what kind of input and opportunities for practice are offered for learners to develop their pragmatic competence (Martínez-Flor & Usó-Juan, 2010). Therefore, classroom research refers to that type of investigation actually implemented in real classrooms which studies what is happening in this particular context.

In order to examine the research conducted in this setting with a focus on pragmatics, it is essential to first present the differences involved in developing pragmatic competence in a second language (SL) or a foreign language (FL) classroom. Then the distinction between research which examines the opportunities offered for pragmatic development in the classroom context (i.e., observational), and research which analyzes the effects that implementing a particular instructional treatment may have on fostering learners' pragmatic competence (i.e., interventional), will be reported. Finally, the different research methods employed in classroom-based studies with a focus on pragmatics will also be addressed.

Differences Between Second and Foreign Language Classrooms with a Focus on Pragmatics

According to Kasper (1989), a distinction exists between *natural contexts*, which refer to those places where learning occurs while the learner is actively engaged in naturally occurring contexts, and SL and FL settings, which are designed specifically for language learning to take place. Whereas the former (that is, natural contexts) are traditionally exemplified by dyadic face-to-face interaction, the latter (that is, SL and FL settings) have been traditionally associated with the type of teaching known as frontal, in which the teacher controls the interaction. The distinction between these two last types of educational settings, namely those of SL and FL classrooms, as well as the advantages or disadvantages they display in providing opportunities for developing learners' pragmatic competence, are key in the field of interlanguage pragmatics.

Regarding opportunities offered for learners' acquisition of pragmatic competence in both types of contexts, the SL classroom offers more advantages than an FL setting for developing learners' pragmatic ability (Kasper, 2001). In an SL context, learners have rich exposure to the target language outside the classroom and a lot of opportunities to use it for real-life purposes. This fact enables them to develop their pragmatic ability, since they may get involved in situations where they are required to interpret utterances in context or interact with different participants in different environments. In contrast, learners in an FL setting lack all these opportunities to be engaged in genuine communication in the target language. Additionally, they do not have a direct observation of native speakers that may provide them with a model to be followed. In fact, the only source of input and instances of pragmatic behavior they may receive comes from the classroom. For this reason, creating the necessary conditions that allow learners to develop their pragmatic competence in this specific context is essential. As Rose (1999) points out, this aspect is also particularly difficult, since FL classrooms involve large classes and limited contact

hours that prevent teachers from organizing an appropriate environment to facilitate the development of learners' pragmatic ability. However, if the FL classroom is somehow homogeneous (a decreasing feature of classrooms in an increasingly multicultural and multilingual world), it may offer the possibility of establishing comparisons between learners' mother tongue and the target language, as well as which pragmatic features may be common to or different in the two cultural systems.

To sum up, SL classrooms involve a series of characteristics that are not observed in FL classrooms, namely those of authentic target language input, interaction in the target language outside the classroom, exposure to diverse contexts, authentic purposes of target language use, and social consequentiality. However, in spite of all the advantages that an SL context may offer for pragmatic development, it has been claimed that even after a long period of contact with the target language, some pragmatic aspects still continue to be incomplete (Bardovi-Harlig, 2001). In this sense, teaching pragmatic competence in both SL and FL classrooms has been regarded as advisable and necessary. According to Bardovi-Harlig and Mahan-Taylor (2003), the classroom is a place where, by means of instruction, salient input may be provided. Moreover, instruction can help learners understand language use and provide them with knowledge of the different choices that may be employed depending on the situation they are involved in and whom they are talking to. (For the elaboration of different activities and instructional approaches to teach a variety of pragmatic features in the classroom setting, see Bardovi-Harlig & Mahan-Taylor (2003), Huth & Taleghani-Nikazm (2006), and Usó-Juan & Martínez-Flor, 2008, among others.) The actual classroom-based research conducted in these settings is reported next.

Research on Pragmatics in the Classroom Context

In an attempt to describe the research conducted on pragmatic-related aspects in the classroom setting, Kasper (2001) distinguishes between *observational* and *interventional* studies.

Observational studies are often conducted in authentic classrooms where the researcher focuses on certain L2 pragmatic issues. The main purpose of these studies involves the analysis of the processes that take place in the classroom by describing in detail any aspects that may influence the acquisition of L2 pragmatics, such as teacher input, chances for productive practice in collaborative activities, or observation of learners' development of pragmatic ability over time. Pragmatic issues can be studied developmentally, by paying attention to the pragmatic development that comes about in the classroom by examining issues related to language acquisition and language socialization, or nondevelopmentally, by paying attention to pragmatic features such as speech acts, discourse markers, classroom discourse organization, or politeness phenomena as they happen at a point in time in the classroom. An analysis of observational classroom-based research on different pragmatic aspects has indicated that both SL and FL classrooms may offer learners opportunities for pragmatic learning. In particular, the studies show that arranging productive activities and making learners interact with other peers provide great benefits for the acquisition of pragmatics, while the teacher-fronted classroom structure can also enable learners to develop their discourse-pragmatic ability (see for example the work by Ohta, 2001).

Interventional studies, by contrast, pay attention to a particular kind of intervention that has been used in the classroom setting to teach learners a specific pragmatic feature of the SL or FL. Thus, in contrast to the observational studies, in interventional research the targeted pragmatic aspect becomes the object of the study and the classroom is seen as a setting in which students may learn as a result of planned pedagogical action directed toward the acquisition of pragmatics. Within this group, Rose (2005) distinguishes three

types of interventional studies, namely teachability studies, instruction versus exposure studies, and studies adopting various teaching approaches.

Teachability studies examine whether a particular pragmatic feature is teachable or not in the classroom setting. This type of study adopts a pretest/posttest design which involves only one group, and is also characterized by adopting an explicit type of instruction. *Instruction versus exposure studies* involve the use of two groups of participants under two different conditions in order to compare whether instruction is better than mere exposure. Thus, they attempt to examine Schmidt's (1993) noticing hypothesis, which implies that exposure to the target language alone is not enough for pragmatics learning. This type of research also follows a pretest/posttest design and the group under the treatment condition is usually characterized by receiving an explicit type of instruction. Finally, the studies which *adopt various teaching approaches* examine the effectiveness of different methods in the classroom context. Among these studies, the two typical types of pedagogical intervention involve explicit and implicit instruction. The explicit instructional approach is based on the provision of metapragmatic information through description, explanation, and discussion of the pragmatic feature being taught, whereas the implicit instruction is operationalized by including particular input enhancement techniques (such as the use of bold text or italics) or recasts that attract students' attention toward the targeted pragmatic feature without explicitly explaining anything about such a pragmatic aspect.

An analysis of these three groups of interventional studies illustrates the positive role that instruction on pragmatics plays in both SL and FL classrooms. Regarding the teachability of pragmatic aspects, results show that a range of different features such as discourse markers, gambits, pragmatic routines, pragmatic comprehension, and a variety of speech acts are teachable (Liddicoat & Crozet, 2001; Safont, 2005). Moreover, the effectiveness of instruction has also been demonstrated in studies in which learners receiving instruction outperform those who are only exposed to the target language (Yoshimi, 2001; Fukuya & Zhang, 2002). Finally, concerning the comparison of different teaching approaches, recent research has indicated that the proper operationalization of the implicit type of instruction may yield similar positive results to those obtained by the use of metapragmatic explanations under the explicit instructional approach (Koike & Pearson, 2005; Martínez-Flor & Fukuya, 2005; Alcón, 2007).

An important decision when conducting any type of classroom-based research on pragmatics, either observational or interventional, is the choice of the method of data collection, since its appropriate use will potentially influence research outcomes.

Research Methods in Pragmatics

Kasper and Roever (2005) claim that the main methodological approaches that have been employed to analyze how target language pragmatics is learnt in the classroom setting can be categorized in three groups, namely those of examining spoken interaction, questionnaires, and self-report data.

The method employed in the first group, that is, *recording authentic discourse*, allows the researcher to observe how participants produce and understand pragmatic information and how they interact in contextual settings, but the researcher has no control over the interaction or over how different variables influence participants' behavior in conversation. In order to gain more control over spoken interaction, observational research resorts to elicited conversations by making use of open and closed role plays. In those cases, interactional data are obtained under controlled conditions, but the relationship of elicited conversation to authentic discourse offers problems of validity. In fact, as Golato (2003) points out, the roles students may be asked to perform are often fictitious or imagined,

and this fact may influence their production when they have to act roles they have never played in real life. In addition, performing role plays, in contrast to authentic conversations, does not have real consequences for the students and, therefore, not only *what* is said but *how* it is said may not reflect real speech. A recent alternative is the collection and analysis of naturally occurring data through, for example, conversation analysis (CA) (Markee, 2000; Huth, 2006; Huth & Taleghani-Nikazam, 2006).

Moving on to the second group, different *questionnaires* have been used to examine FL learners' pragmatic competence in the classroom context. Discourse completion tests have been used to collect pragmatic production of speech act strategies, multiple-choice questionnaires serve to measure recognition and interpretation of utterances, and scaled-response formats have been utilized to evaluate learners' perceptions of pragmatic errors or appropriateness of speech act realization strategies. Among them, the discourse completion test has been the most commonly used in research on pragmatics in classroom settings (Hinkel, 1997; Billmyer & Varghese, 2000; Safont, 2005).

Finally, in relation to the third group, which involves *self-report data*, three main methods have been identified, namely those of interviews, think-aloud protocols, and diaries. These three types of self-report methods are characterized by being totally open-ended and more directed toward analyzing participants' behavior and their decisions on the particular pragmatic aspects examined (DuFon, 1999; Woodfield, 2008). Although this third type of method involving self-report data may provide information on learners' cognitive processes, it has not often been used in classroom research on pragmatics. One reason could be that qualitative data is more time-consuming than the administration and analysis of questionnaires, and it is also more difficult to generalize the results obtained. However, a qualitative type of methodology is needed if we follow a sociocultural or socialization perspective in research on pragmatic learning. In this case, CA may be used to examine in detail how opportunities for pragmatic learning arise in different contexts, and interviews and self-report data may be assessment measures from which we can choose the one that best suits our purposes.

Overall, research on pragmatics in classroom contexts, in either SL or FL settings, shows the positive role of engaging learners in an instructional period (by implementing either an explicit or an implicit instructional treatment) and the teachability of all pragmatic aspects examined (i.e., a variety of speech acts, implicature, pragmatic particles, or presupposition, among others). A common consideration in all this research is the importance of exposing learners to rich and contextually appropriate input, as well as providing them with ample opportunities to communicatively practice the particular pragmatic feature being taught. Additionally, the issue of choosing the most appropriate research method taking into account the objectives to be achieved in a particular classroom-based study is also of paramount importance. In fact, the method of data collection has been reported to potentially influence research outcomes, and that is why it is advisable to adopt a multi-method approach that involves the use of different instruments in all classroom research on pragmatics, to maximize information and increase the level of objectivity of findings.

Classroom Discourse

ANDREW JOCUNS

Classroom discourse, broadly defined, refers to all of those forms of talk that one may find within a classroom or other educational setting. However, a review of the literature reveals that the context of what makes up classroom discourse as a unit of analysis is quite broad, and perhaps a better way of thinking of this unit is to broaden the scope of the term to discourse in educational settings. The analysis of classroom discourse has evolved from studies that examined teacher and student interaction to a more recent emphasis on learning and identity construction through discourse. The range of topics included within classroom discourse analytical studies has also ranged from such topics as literacy and teacher–student interaction to a more recent emphasis on multimodal semiotics and interactions in STEM classrooms (science, technology, engineering, and mathematics). In addition the breadth of research on classroom discourse has ranged in scope from microanalytical conversation analysis to Halliday’s systemic functional grammar (1978, 1994). While many linguists have fostered the development of classroom discourse, it should also be noted that education research has evolved its own paradigmatic approaches to classroom discourse (e.g., interaction analysis). This selective review will begin by examining some seminal texts in the study of classroom discourse focusing first upon ethnographic studies, then offer a discussion of the influence of conversation analysis in the study of classroom discourse, and finally highlight some recent trends in the study of this phenomenon including knowledge in classroom discourse and research in STEM classrooms.

Culture and Socialization in Classroom Discourse

It goes without saying that the history of social science theory and practice has involved an ever shifting unit of analysis relative to the theory or practice to which a researcher adheres. Some of the most seminal studies of classroom discourse were rooted in linguistic anthropology, and more specifically derived from the ethnography of speaking. Such studies focused upon the variation of how language is socialized not only across languages but other spoken varieties and dialects as well. Cazden, John, and Hymes’s (1972) edited volume provided a series of studies that was meant to emphasize how language was often misused in schools such that minority students were left out largely because they had no forum in school with which to utilize the linguistic practices that they were socialized in. That is, schools failed to consider the effects of native languages and dialects in curriculum development. Cazden (2001) has suggested that, in order to offer a more inclusive classroom, discourse behavior should be explicitly taught in classrooms, enabling students who are excluded from success because of issues of mismatched linguistics practices to participate fully in the classroom.

Another such study rooted in the ethnography of speaking was Philips’s (1983) study of the Warm Springs Indian Reservation. Philips noted problems in how White teachers interacted with Native American students in the classroom. The students in question were socialized to interact differently with adults than their Caucasian counterparts. Philips identified the interactive means behind this discrepancy and defined the concept of participant structures—ways of arranging verbal interaction for students. Additionally Philips

2 CLASSROOM DISCOURSE

isolated four participant structures that were used in the classroom that conflicted with those the Native American students were socialized in and utilized in their own homes. This study revealed that culture and socialization play a key role in how students are perceived by their teachers in the classroom. Students who were socialized in the dominant culture were more familiar with the participant structures used in the classroom, and as such, had a better chance at success. The analysis of participation structures has gone well beyond the classroom but has endured as an important analytical category with which to study classroom discourse ethnographically. In a more recent study of Balinese Gamelan classrooms in the United States, Jocuns (2009) emphasized how students are active participants in classrooms, and at times, may choose which participant structure to use at a given moment.

An equally important strand of research in classroom discourse and cultural difference has been the work of Gumperz. From Gumperz's work came the important understanding of conversational inference—the situated or context-bound process of understanding amongst participants—and contextualization cues—verbal signs produced during interaction that enable the process of conversational inference to occur. Cook-Gumperz and Gumperz (1982) argue that an important consideration for studies of classroom discourse and interaction is the notion of communicative competence. Communicative competence refers to what a speaker needs to know in order to be a competent speaker within a community. As Philips (1983) has shown, what makes one communicatively competent within a community may not make one competent within an educational setting. What is more, Cook-Gumperz and Gumperz (1982) contend that there is a vast difference between ways in which people learn the world over. That is to say, cultural differences in discourse style and behavior do not end with a discussion of linguistic practices, but should also include cross-cultural examinations of learning practices.

The early studies of classroom discourse that focused upon differences in how groups of people are socialized and how that affects classroom experiences and performance eventually bled into other areas of language use in the classroom, most notably literacy studies. Several researchers found that literate practices, similar to discursive practices, were vastly different in school contexts compared to the communities from which students were socialized. Shirley Brice Heath's (1983) study of multiple communities in Appalachia discussed how not only linguistic practices differed in terms of socialization across communities, but the expectations of literacy practices also differed across these cultural traditions. Scollon and Scollon's (1981) study drew attention to the differences between literate practices of textual literacy and oral literacy in Arctic Village, Alaska. In addition, there is a growing body of research in the new literacy studies which has effectively drawn attention to the fact that not only are there different cultural practices of literacy, and different values placed on literacy, but also that literate practices have implications that go well beyond the classroom itself (Gee, 1996). One of the implications of these studies of cultural differences between language use and literacy practices, and between the community and the classroom, is that what counts as knowledge varies across these contexts and success in the classroom implies a comprehension of the dominant culture's use of linguistic and literate practices (Bloome et al., 2005).

A recent trend within classroom discourse analysis has involved the positions taken up by students and the role of teachers in the development of classroom and educational identities. Wortham's (2006) study of students in a great books course in middle school has drawn attention to how academic learning and processes of social identification can be dependent upon one on another. Wortham develops his thesis based upon two students whose identities evolved along their trajectories of identification in unexpected ways where the students in question were identified by their teacher and classmates as having identities and character traits similar to curricular themes that emerged in the class. From this study

we learn how processes of social identification emerge within classrooms, along trajectories of identification, over both time and space and that social positioning (i.e., identity development) and academic learning are dependent upon one another.

The Microethnographic Study of Classroom Discourse

Influenced in part by the conversation analysis tradition, there is a large body of research in education and classroom discourse that has focused upon the real-time moment-to-moment interactions between teachers and students. This is not to suggest that those studies that utilize the ethnography of communication do not examine real-time language use, but such studies tend to be more holistic and focus upon larger cultural differences. Conversation analysts argue that social structures are discerned and reproduced in how participants interact. As such the analytic structures that make up the conversation analysis tradition, such as turn structure, repair, and interaction sequences should emerge during classroom interaction between teachers and students and reveal some aspects of the social structure that holds classrooms together. In addition, as noted in the previous section, the structures of the dominant and minority cultures emerge as well. One example is question and answer sequences, and as Heath (1983) found in her study, there were differences in how the communities in her study valued and used such question and answer pairs in the home compared to how they were expected to be used in the classroom.

In his work on the structure of classroom behavior, Mehan (1979, 1985) noted that one difference in how teacher–student interaction emerges in the classroom, as compared to normal conversation, is that in the classroom there may also be an evaluation component that is attached to the end of the interaction by the teacher. A widespread finding, and one that has continually received much attention, from studies of classroom discourse turn sequences has been the initiation–response–evaluation, or I–R–E, conversational turn structure (Mehan, 1979). Within this structure a teacher may ask or initiate a question, delegate a student to respond, and based upon the response evaluate the accuracy of the student’s response or offer other types of feedback.

There have been several interpretations and criticisms of the I–R–E structure that are worthy of note. Wells (1999) refers to this structure as IRF where the F refers to feedback or follow-up; this is to emphasize that the teacher is not always evaluating the student’s response as positive or negative. One interpretation is that the I–R–E limits student participation to short brief answers, limited in scope to what the teacher knows, and as such not conducive to more complex types of learning to include: developing intricate responses, dealing with ambiguously composed texts and constructing alternative interpretations (Bloome et al., 2005). Another issue with I–R–E that Bloome et al. discuss is that on the surface it appears as if the I–R–E is a linear pattern of social interaction, when in fact it can, and often does, occur alongside many classroom interactions that may be occurring simultaneously. One of the many criticisms surrounding the I–R–E is that evaluation is not always present and that while many classroom discursive interactions between teachers and students resemble the I–R–E structure, it is obtuse and meaningless to be analytically confined to the structure itself (Wells, 1999). Rather, many researchers suggest going beyond the I–R–E in order to effectively evaluate the quality of the interaction. Others have suggested that the structure itself is bound by a complex power relationship between teachers and students and by using the I–R–E a teacher is able to exert authority and power within the classroom. Another interpretation of this structure is worthy of note here, as it relates to processes which are going on in real-time conversations outside of the classroom, and that is the construction of common ground and intersubjectivity. This body of work suggests that the seeming gatekeeping behavior of the teacher who utilizes the I–R–E structure

4 CLASSROOM DISCOURSE

is not to limit what the students contribute as much as it is to manage the information and knowledge that is conveyed through the lesson and as a result develop “common knowledge” amongst the students and teacher (Edwards & Mercer, 1987).

Erickson (1996) notes that the variety of interactions that emerge within a classroom are not always representative of the simple I-R-E structure, but rather include a complex array, or ecology, of behaviors that have social and cognitive implications for the participants involved. The emergent discursive behavior of classrooms is not always represented accurately by the I-R-E structure. Jocuns (2007, 2009) investigated the pedagogy used to teach Balinese Gamelan known as *maguru panggul* (the teacher is the mallet) and those findings suggest a different format for the I-R-E as it emerges in different types of classrooms. In a music classroom the teacher is constantly evaluating the behavior of music students and addressing problems as they arise in real time. The important goal is establishing common ground and shared knowledge between the teacher and the music students. This suggests that the structure of turn sequences is not uniform across educational settings and that the goal of such structures is not necessarily to maintain control and power, but for the teacher to establish shared knowledge, that is, intersubjectivity, amongst the teacher and students (Edwards & Mercer, 1987). Another body of recent work in classroom discourse has involved studies of multimodal discourse analysis where researchers draw on large stores of digitized video data to analyze the behavior in classrooms. One such approach has also introduced Halliday’s systemic functional grammar to the analysis of classroom discourse, most notably the work of Wells (1999).

Knowledge and Classroom Discourse

One approach to classroom discourse has been to examine not only the language that is used within the classroom or educational setting but the myriad of ways in which knowledge is constructed, displayed, or both during social interaction within the classroom, not to mention content knowledge. These studies build on ideas discussed in the previous section, namely those that emphasize how classroom discourse involves a negotiation of shared knowledge between teachers and students (Edwards & Mercer, 1987). Such studies have examined the metacommunicative knowledge at a student’s disposal during learning interactions including verbal and nonverbal discourse, and the participant structures available for a student to use in a specific educational setting (Jocuns, 2007, 2009). In addition, studies have shown how the discursive strategy used in a classroom influences the co-construction of knowledge and identity in the classroom (Duff, 2002). A common theme of studies of knowledge and classroom discourse has also been the negotiation and re-negotiation of knowledge between teachers and students (Tuyay, Jennings, & Dixon, 1995). The crux of such studies is that they emphasize that students learn more than just content knowledge during classroom interaction: they also learn the metacommunicative means by which to construct knowledge, as well as the ability to develop and maintain social roles and identities. What is more, through classroom discourse students play a role in constructing content knowledge.

Discourse Analysis in STEM Classrooms

An ever increasing body of research in classroom discourse has examined the language used in teaching mathematics and science in classrooms and laboratories, as well as how language in the science classroom is influenced by science textbooks. Interestingly many of these studies are influenced by Halliday’s social semiotics. In addition to showing how language is used differently in science activity, in terms of how scientists in laboratory

meetings blur the distinction between the scientist and the physical world (Ochs, Gonzales, & Jacoby, 1996), such studies of the science classroom emphasize the importance of a multimodal approach to the science classroom. Lemke (1990) has shown how the specific language of science is used to talk about the work and that in order to “talk science” students in the science classroom must acquire this language to be successful. Kress, Jewitt, Ogborn, and Tsatsarelis (2001) examined how the nature of scientific discourse is multimodal and as such students must acquire not only the skills to talk about science, but also the multimodal interactional skills to learn in the science classroom. Using a systemic functional approach Young and Nguyen (2002) show how modes of teaching and learning are influenced by different modes of communicating. In their case they examine the differences in language used in a textbook compared to the verbal interactions of the teacher. Similarly, others have shown how students in the science classroom experience the science curriculum through both verbal interactions and written text, and that different science texts promote different types of interactional engagement and as such promote different types of discourse (Kuipers, Viechnicki, Massourd, & Wright, 2008). Another body of research in STEM classrooms focuses upon the fact that, in order to be successful in a STEM class, students must become members of a community of speakers (Sfard, 2007). Discourse analysis in the science classroom involves situating the science textbook within the interactive framework of the classroom and in some instances the text is resistant to talking science.

This entry began with a juxtaposition of two approaches to classroom discourse—the ethnography of communication and conversation analysis—followed by a short discussion of a few approaches that utilize systemic functional grammar. Rampton, Roberts, Leung, & Harris (2002) provides a complete and thorough description of these three theoretical traditions as they are related to research work in applied linguistics and the analysis of classroom discourse. While these three traditions do represent the main three theoretical angles to approaching discourse in educational research it should be noted that most analyses are not confined solely to one of these three approaches, but often utilize an eclectic mix of theories and studies including those found in qualitative traditions of educational research.

Classroom Research

NINA SPADA

Classroom research (CR) in applied linguistics has evolved from descriptions of pedagogic practices used primarily for second/foreign language (L2) teacher training purposes, to experimental investigations of the effects of instruction on L2 learning, to analyses of a wide range of learner factors that are thought to contribute to more (or less) successful learning. Below CR is defined along with a description of how it has evolved, how it has been conducted and the types of questions and topics that have been investigated.

What Is Classroom Research?

According to Allwright (1983), “Classroom research is just that—research centered on the classroom . . . it simply tries to investigate what happens inside the classroom when learners and teachers come together.” (p. 191). More recently, Dörnyei (2007) described CR as “an umbrella term for empirical investigations that use the classroom as the main research site” (p. 176). This emphasis on the classroom as the context in which research is carried out is critical because not all research that claims to have implications for L2 learning and teaching actually takes place in classrooms. Nunan (1991) emphasized this point in a review of 50 widely cited studies examining relationships between L2 teaching and learning. He found that only 15 of them had been carried out in authentic language classrooms. Most of the studies were conducted in a laboratory or quasi-laboratory setting and thus were more appropriately referred to as “classroom-oriented” research. Nunan argued that “if context is important to research outcomes, then we need more classroom-based . . . studies” (p. 103). In the years since Nunan’s review, more research has been carried out in L2 classrooms.

What Are the Origins of L2 Classroom Research?

CR emerged as a clearly identifiable area of research in applied linguistics in the early 1960s. It was at that time that the “method comparison” studies were underway to investigate the effects of the audio lingual versus the cognitive code method on L2 learning (e.g., Chastain, 1969). These large-scale experimental studies indicated no superior advantages for one teaching method over the other but the results were difficult to interpret because no information had been collected about how the different instructional methods had been implemented. This was a serious limitation of the research because teachers are known to implement the same method in different ways. Even when different labels are used to characterize different methods, they often overlap in several ways. This was confirmed in a replication of the “method comparison” studies carried out 20 years later with the inclusion of a classroom observation component. The results indicated overlapping instructional practices in the two experimental groups and no advantages for one L2 teaching method over the other (Swaffar, Arens, & Morgan, 1982).

The realization that the “method comparison” studies failed to take account of what actually happened in classrooms led researchers to develop studies in which teaching and learning behaviors in L2 classrooms were systematically described.

Are There Different Approaches to Classroom Research?

In his comprehensive book on research in second language classrooms Chaudron (1988) identified four traditions in classroom research: *psychometric*, *interaction analysis*, *discourse analysis*, and *ethnographic*. The psychometric approach involves experimental and control groups and measurements of learning outcomes. It was used in the “method comparison” studies discussed in the previous section and has also been used in more recent CR on instructed second language acquisition (SLA) some examples of which are presented below.

Interaction analysis, influenced by sociological investigations of group behaviors in first language classrooms, is characterized by the use of observation schemes to describe and analyze teacher and learner behaviors. Over 30 observation schemes have been developed for use in L2 classrooms and they vary in number and type of categories and focus. For example, one well-known L2 observation scheme, the *Communicative Orientation of Language Teaching Observation Scheme*—COLT (Spada & Fröhlich, 1995) focuses on pedagogical practices and linguistic behaviors of teachers and learners. This contrasts with a recent observation scheme, *Motivation Orientation in Language Teaching*—MOLT (Guilloteaux & Dörnyei, 2008), which focuses on aspects of teachers’ motivational practice and learners’ motivational behavior.

Discourse analysis, “arose from a linguistics perspective in an attempt to analyze fully the discourse of classroom interaction in structural-functional linguistic terms” (Chaudron, 1988, p. 14). This approach is characterized by detailed descriptions and analyses of the speech produced by teachers and learners. While there have been analyses of the entire discourse in some first language classrooms, most L2 research has focused on particular aspects of discourse for detailed study (e.g., question types, corrective feedback). Contemporary research in critical discourse analysis in L2 classrooms represents an epistemological shift from traditional discourse analysis taking the view that “classroom discourse like all other discourses, is socially constructed, politically motivated, and historically determined” (Kumaravadivelu, 1999, p. 472).

Ethnographic CR originated in cultural anthropology and the tradition of describing and analyzing the practices and beliefs of different cultures through the use of rich narratives including field notes, diaries, journal entries, film, and audio recordings. Although it took some time for ethnographies of L2 learning to appear on the CR scene, they are a recognized research tradition in L2 learning and teaching and span a wide range of topics (van Lier, 1988). Examples of ethnographic research in L2 classrooms include detailed descriptions and comparisons of ESL student identities and social relations and how these impact on classroom practice and students’ academic and linguistic progress (Toohey, 2000).

While these four traditions represent distinct approaches to CR situated within different theoretical and empirical frameworks, they are increasingly combined in CR studies. Classrooms are highly complex environments including instructional and social components. Thus, researchers increasingly agree that CR benefits from the use of multiple methods and techniques for data collection and analysis.

What Type of Questions and Topics Are Examined in CR?

A wide range of questions and topics have been investigated in CR some of which have already been referred to above. One of the main areas of CR is the kind of linguistic input that learners are exposed to either through teacher talk or instructional materials. This includes investigations of the way in which L2 instructors modify their speech using strategies such as repetition and paraphrasing to aid learner comprehension. Some recent work has examined the extent to which other sources of input (e.g., simplified texts) promote

comprehension and learning (Horst, 2005). Another central area of CR has focused on the type of questions that teachers ask (e.g., closed versus open; genuine versus display) and how this contributes to the quantity and quality of learner production. One recent example is a detailed discourse-based analysis of question types in content and language integrated learning (CLIL) classrooms in Austria (Dalton-Puffer, 2007).

A good deal of CR has investigated the different types of corrective feedback teachers provide to learners, whether some types occur more frequently than others and in what instructional contexts. CR has also examined whether learners notice certain feedback types more than others, if they respond differently to feedback types and whether particular types of corrective feedback contribute more to L2 learning (Lyster, 2007). In addition, classroom-based studies in the instructed SLA literature have examined the effects of different types of instruction on L2 learning (Spada, 2011). CR also includes studies that have investigated interactions between different types of instruction and characteristics of individual learners (e.g., aptitude) and their combined effects on L2 learning (Erlam, 2005).

Future Directions in CR

One of the claims that researchers make about CR is that the findings are likely to be considered as more relevant and meaningful by L2 teachers and practitioners because the research is carried out with real teachers and learners in real L2 classrooms. While this greater “ecological validity” may be true, the challenges of carrying out research in authentic classrooms are many, not least of which is the lack of control that researchers have in such contexts. The debate about the “ecological validity” of CR has intensified in recent years and is likely to attract more research attention in the future.

Classroom Research in Second Language Acquisition

JOAN KELLY HALL AND DUFF JOHNSTON

A sociocultural perspective of language and learning has had a major impact on classroom research on second language acquisition (SLA) over the last two decades. This perspective considers language to be a fundamentally social phenomenon, comprised of linguistic resources whose meanings are both embodied in and constitutive of everyday communication. Language learning is viewed as a collaborative process that begins in our regularly occurring communicative activities. Through repeated experience and the guidance of more capable others, individuals acquire not only the grammatical, lexical, and other communicative resources essential to full participation, but also the communicative intentions and specific perspectives on the world that are embedded in these resources.

These views of language and learning have drawn attention to the importance of language classrooms as sociocultural communities in their own right and as communities embedded in larger social worlds. While these communities may be characterized by shared goals, resources, and patterns of participation, they may also serve as sites of conflict involving divergent values, motivations, and resources. Crucial to the accomplishment of classroom communities, whether cooperative or not, are the interactional activities created in teacher–student and student–student talk. Through their interactions with students teachers provide models of what they consider appropriate language knowledge and skills for use as well as strategies and opportunities for students to acquire them. In the process of participating in these interactions and those involving their peers, learners position themselves in relation to different patterns of interaction and to the roles, relationships, and goals made available through these patterns. In the process, learners develop habits of language use with which they make sense of and participate in their classroom communities. It is their eventual internalization of their activities' linguistic resources, including the particular worldviews embodied in them, which characterizes classroom language learning.

What follows is this. After briefly summarizing the disciplinary foundations of second and foreign language classroom research informed by a sociocultural perspective, we review current research trends and conclude with a brief discussion of future directions.

Disciplinary Foundations and Early Research

A sociocultural perspective on classroom-based SLA draws on several disciplinary fields for theoretical and methodological inspiration. A first source of insight is found in the tradition of American linguistic anthropology, and in particular, the work of Dell Hymes, John Gumperz, and Elinor Ochs. In contrast to a view of language as a universal, fixed property of the human mind, Hymes (1964) considered social function to be the source of linguistic form, and so proposed the ethnography of communication as a conceptual framework and method for capturing patterns of social action and their linguistic components as used by members of social communities in real-world contexts. A contemporary

of Hymes, Gumperz (1982) was also interested in the social foundations of language. Labeled interactional sociolinguistics, his approach to the study of language use focuses on the identification of linguistic and prosodic cues social group members use to index contextual meanings, and specifically on those moments where interpretive differences in cue use lead to miscommunication. Building on the work of Hymes and Gumperz, and drawing on empirical data gathered from caregiver and other activities within family groups, Ochs (1988) proposed language socialization as a conceptual framework for understanding the interdependence of language and culture learning. A key premise of this framework is that through its use in interaction, language socializes individuals not only into appropriate and meaningful patterns of language use but also into particular identities and social relationships, and more generally into systems of thoughts, beliefs, and values specific to their groups.

Drawing on these insights, early classroom research used ethnographic methods such as participant observation and audio and video recordings to capture patterns of communication found in classrooms; these were then examined for the kinds of opportunities for learning they made available to learners. While some researchers in the 1980s drew on these insights to study interaction in classrooms that included linguistically and culturally diverse students, such research did not gain currency in studies of second and foreign language classrooms until the 1990s. Some early studies conducted during this time include those by Poole (1992), Harklau (1994), Willett (1995), and Toohey (1998). Drawing on the language socialization paradigm, Poole examined teacher–student interactions in two ESL (English as a second language) classes in terms of the cultural norms and beliefs regarding expert accommodation of novice incompetence and displays of knowledge into which the students were being socialized. In a similar vein, Harklau compared patterns of spoken and written language use in an ESL classroom to those in a mainstream classroom and found significant differences in terms of the curricular content and goals and instructional practices. She argued that these differences had different socializing effects and thus led to differential treatment of the ESL learners.

Also drawing on the language socialization paradigm are the studies by Willett (1995) and Toohey (1998), who examined the socialization practices found in elementary classrooms that included ESL learners. Together, their findings reveal how children's involvement in different routines with their teachers led the teachers to develop different perceptions of learners' language abilities. These perceptions, in turn, led to further differentiation in the kinds of learning opportunities the teachers made available to the learners, which influenced the children's subsequent language and academic development. Although most of the early studies focused on learning contexts of ESL learners, a few examined foreign language classroom contexts. These include Duff's (1995) study of the interaction patterns in a content-based immersion classroom in Hungary, Hall's (1995) study of teacher–student interaction in a high school Spanish-as-a-foreign-language classroom, and Lin's (1999) study of the classroom interaction patterns found in junior form EFL (English as a foreign language) classrooms in Hong Kong.

Another early source of inspiration for classroom research comes from ethnomethodology, a branch of sociology, and specifically, conversation analysis (CA). Asserting interaction as the fundamental site of human sociality, CA seeks to describe the structures used by social group members to bring about and maintain social order in their interactional activities. One early influential study on the interactional accomplishment of educational activities emerging from this paradigm is the 1979 study by Mehan in which he revealed the formal structure of teacher-directed lessons in first language elementary classrooms to be a three-part exchange of teacher initiation, student response, and teacher evaluation (IRE). While this paradigm had some influence in discussions on second and foreign language classrooms in the 1980s and early 1990s, it was not until the late 1990s that interest

developed in using CA to examine the routine activities of second and foreign language classrooms.

A third source of inspiration comes from developmental psychology and in particular Vygotsky's theory of learning (Vygotsky, 1986). A key premise of this theory locates the source of learning in social activity mediated by symbolic means. These means are the linguistic tools and other resources with which more expert members assist less competent participants in noticing, ordering, representing, and remembering their involvement in communicative activities. On this view, individual learning is fundamentally tied to its specific contexts of learning and the means by which they are constituted. These contexts and their means are what eventually become the cognitive tools with which learners make sense of and participate in their communicative worlds. Early language classroom research invoked different Vygotskian concepts such as regulation, private speech, scaffolding, and the zone of proximal development (ZPD) to examine the linguistic means used by teachers and students to create and participate in various learning activities. Representative studies include Adair-Hauck and Donato (1994), which examined the means by which teachers scaffolded learners in the ZPD; de Guerrero and Villamil (1994), which examined the effects of ESL peer mediation in the ZPD; and McCafferty (1994), which examined the role of L2 learners' private speech.

Current and Future Directions

While these trends in classroom research continued throughout the 1990s, they did not begin to take a firm hold of the field until the early years of the new millennium. This increased interest was due in part to scholarly discussions in the late 1990s that called for expanding the theoretical, conceptual, and methodological scope of the field. While earlier research could be characterized by allegiance to its disciplinary roots, current trends are taking a more synergistic approach that merges disciplinary boundaries. For example, current ethnographic studies of classrooms with interests in language socialization have also drawn on social anthropological research and specifically on Lave and Wenger's (1991) community of practice model. In this model, novice community members start as legitimate peripheral participants who gradually become experts through the language they learn to use in routine patterns of interaction. Two examples of studies adopting this extended model of language socialization are He's (2003) study on the varied ways Chinese heritage language learners participated in classroom interactions and Vickers's (2007) study of the professional L2 socialization of an ESL student in an undergraduate computer engineering course. In contrast to earlier work, these more recent studies emphasize that the second and foreign language socialization of learners does not necessarily follow a smooth or predictable course. While inclusionary efforts of more expert community members play a major role in learners' socialization, a variety of other social, historical, and political issues may influence the developing participation of these novice members. Taken together, these efforts reinforce the importance of sensitivity to local conditions of use and the specific, situational needs and practices of learners and instructors.

Another hallmark of current ethnographic research is its critical view of classrooms. In contrast to earlier work, which depicted classrooms as largely unproblematic learning environments, current research highlights the potential for conflict between instructional goals and learner outcomes. In addition, a second group of studies has begun the vital work of examining the social contexts of foreign language education in developing areas outside traditional Western research settings. Representing the first group of studies is Duff's (2002) examination of interaction in a mainstream Canadian high school social studies class. Her findings reveal how instructor strategies for including ESL students,

such as asking them to discuss what, to the students, were sensitive issues, and the regular interruptions by native English-speaking peers, worked together to reduce ESL students' participation rather than enhance it. Similarly, Nguyen and Kellogg (2005) reveal how instructor objectives and peer pressure in an adult ESL class led to relatively low frequency of electronic message board postings by learners who disagreed with course content favoring a tolerance of diverse sexual orientation. As an example of ethnographic classroom research in a non-Western setting, Blommaert, Muyliaert, Huysmans, and Dyers' study (2005) of English classes at a multilingual and socioeconomically disadvantaged community high school in South Africa reveal how local community practices of L2 use and instruction worked to reinforce locally appropriate but internationally divergent language models. The authors argue that the peripheral normativity reproduced at the school may be typical of second and foreign language learning in many developing areas of the world. Such studies provide a detailed, ground-level understanding of how dominant language models are shaped by local stakeholders to fit their immediate purposes. What both groups of studies emphasize are the challenges inherent in using the social and communicative resources of classrooms to further the language learning of students with varied identities and a wide range of social, affective, and linguistic needs.

Another current trend extends interest in the sociology of second and foreign language classrooms by using CA methods to describe the structural properties of classroom interactional activities, such as the pedagogical practice of directing learners to spot and correct errors (Koshik, 2002), the construction of a small group activity (Mori 2002), and openings of pair tasks (Hellermann, 2007). Relying primarily on detailed transcripts of naturally occurring audio- and video-recorded interactions and paying close attention to the fine points of interaction, the studies make visible the detailed and complex work that language teachers and learners do with their talk to build and manage their classroom worlds.

A final area of focus of contemporary socioculturally grounded classroom research continues to use Vygotskian concepts to investigate teaching and learning interactions, with increasing interest in the role of student-student interaction as resource in addition to teacher-student interaction for working in learners' ZPDs. Guk and Kellogg (2007), for example, found complementary roles for the two types of interaction by noting that teacher-student interaction produced shorter, form-focused exchanges, while student-student interaction produced longer, more meaning-focused exchanges in Korean EFL classrooms. Similarly, Huong (2007) found that classroom groups that included a more proficient student from a more advanced class used more English in their discussions and were exposed to a higher number of new lexical items when compared to unassisted groups comprised of students at the same proficiency level. Both studies provide arguments for the role of other-mediated learning in the classroom, with a particular emphasis on the role group work can play in developing learners' language knowledge and use.

Most recent is the developing interest in dynamic assessment (DA), which extends the concept of other-mediation in situations of formal language assessment. In contrast to traditional assessment measures that test students in conditions of unmediated isolation, DA seeks to gain a more accurate picture of a learner's ongoing and potential development by allowing them to interact with more knowledgeable partners during the completion of assessment tasks. As one example, Poehner (2007) examined DA sessions involving university-level learners of French describing short film clips to an instructor while using the perfective and imperfective aspects. In interactions with the learners, the instructor asked about problematic aspect choices in order to gauge learners' conceptual understandings while also successfully encouraging them to make more accurate choices. Studies like this make a case for a social view of language learning that treats assessment measures as opportunities for continued language development through the interactional mediation of others.

Socioculturally grounded classroom research on SLA has made significant contributions to our understanding of language classrooms. We understand more fully the complexities of these contexts of learning, and in particular, of the kinds of activities and events typical of different types of classrooms. Likewise, we have gained an understanding of how the social, economic, historical, and political conditions of larger social communities give shape to the types of learning communities that are created in language classrooms, and, more particularly, the varied roles that teachers and students play in their learning communities, and the subtle yet significant influences that teachers' and students' understandings of their roles have on the learning environments they create. We also understand more fully the intricacies of interactional patterns and other means used to mediate learners' language development.

These accomplishments notwithstanding, much work remains to be done. In this final section we briefly chart what we feel are promising directions for future research on classroom-based second and foreign language learning. A first direction is toward greater integration of the conceptual and methodological perspectives outlined above. Although this entry has largely presented these perspectives in isolation for clarity's sake, an honest appraisal of existing research finds considerable cross-pollination among them, with scholars regularly invoking a principled eclecticism in merging insights, concepts, and methods from several fields in order to conceptualize and describe the complex interactional dynamics they find in language classrooms. Typical of this approach is the work of Hellermann (2008), who embeds conversation analytic examinations of learner–learner interactions in adult ESL classrooms within a community of practice framework. While proponents of conceptual and methodological orthodoxy will undoubtedly question such attempts at research synergy, socioculturally minded classroom researchers will continue to draw on a diversity of ideas and methods to illuminate and build understanding of the myriad details of classroom language learning contexts.

A second direction for future research involves the continued development of critical language classroom assessments. Following current research that problematizes the interactional affordances and outcomes for learners, future studies should continue to develop rich descriptions of classrooms that highlight the potential for contested interactional goals and activities. Key to these studies will be fuller descriptions of classrooms as cultural contexts with their own sites of struggles and their own local institutional imperatives that both support and contradict the social and linguistic needs of learners. Also key will be the inclusion of examinations of interactions that occur both at the margins of formal lessons and within them, such as small talk, storytelling, joking, and other interactional activities by which friendships and other relationships are built and managed, and the kinds of learning opportunities they engender.

A third direction involves an expansion of classroom-based studies beyond the Western research core to include work in what have traditionally been considered peripheral, developing contexts. In addition, efforts to explore a fuller range of language learning at all levels of formal education—including, most significantly, elementary and secondary levels—will undoubtedly be a feature of future studies as researchers explore the socio-cultural implications of classroom-based learning.

Finally, as research continues to explore a wider range of classroom contexts and to connect them more closely with the varied communities that language learners also inhabit, there is still a need to connect descriptions and findings with efforts to address the challenges and inequalities that are revealed. As we move more fully into the twenty-first century, one mark of effective socioculturally grounded research on second and foreign language classrooms will be the ability of researchers to establish and maintain productive collaborative relationships with educators, parents, policy makers, and other community stakeholders aimed toward nurturing effectual practices of language teaching and learning in classrooms that are indigenous to their particular social contexts.

Cluster Analysis

KATA CSIZÉR AND JOAN JAMIESON

“Cluster analysis is the art of finding groups in data” (Kaufman & Rousseeuw, 1990, p. 1). Cluster analysis is a cover term for a variety of exploratory techniques which aim to classify observations into subgroups based on their similarities to each other, and their differences from members in other subgroups, based on a set of predefined characteristics. Observations that applied linguistics researchers might want to classify as cluster analysis depend on the subfield: in discourse analysis, various texts might be grouped by using linguistic features and different registers as clustering variables; in testing, test tasks might be grouped using types of input and difficulty indexes as clustering variables; in second language acquisition, learners might be grouped using individual difference variables such as students’ attitudes and motivation as clustering variables. Researchers should take into account the fact that this procedure is considered to be exploratory (Kojic-Sabo & Lightbown, 1999; Dörnyei, 2007); that is, it usually describes groups of observations or participants but does not test hypotheses; effect size is not considered.

Overview

Cluster analysis is distinguished from other data-reduction techniques, such as factor analysis and discriminant analysis, by the fact that with many cluster analysis techniques there is no assumption of an underlying statistical model (Arabie & Hubert, 1996; Everitt, Landau, & Leese, 2001; Norušis, 2010). As Dörnyei (2007) puts it, “currently cluster analysis lacks an underlying body of universally endorsed statistical theory. Thus, researchers need to make several somewhat arbitrary decisions relating to the method of calculation” (p. 237). Researchers not only face this dilemma but also a general lack of agreement on how a “cluster” is defined and the computational difficulty of finding nonoverlapping clusters in all but the smallest of data sets (Milligan, 1996).

A number of techniques are available in cluster analysis, including graphs, partition or proximity (both names are used), hierarchical, fuzzy analysis, and the more statistically sound methods of classification likelihood and finite mixture models (Everitt, personal communication, May 13, 2010). The two most common techniques are hierarchical and partition/proximity (Kaufman & Rousseeuw, 1990). Hierarchical techniques compute as many clusters as there are observations, in iterative runs, which is very intensive for large data sets. There are two types of hierarchical techniques—agglomerative methods and divisive methods (Kaufman & Rousseeuw, 1990). The most common, agglomerative methods, start with as many clusters as there are observations and end up with one cluster. First, the closest individual members of the sample are grouped into new clusters, and then the closest clusters are joined together until one single cluster containing all sample members is arrived at.

Divisive methods do the opposite; they begin with one cluster and end up with as many clusters as there are observations. In both techniques, once an observation has been assigned to a cluster it cannot be reassigned. Partition/proximity techniques classify data into k clusters, in which each cluster must contain one observation, and each observation must belong to only one cluster. The number of clusters is predetermined by the researcher,

2 CLUSTER ANALYSIS

which is seen as a drawback because results are highly dependent on this initial choice. All of these techniques produce a series of partitions in the data by using one of several clustering measures. Similarity measures are frequently used for categorical data and for data containing both continuous and categorical variables, while dissimilarity measures (i.e., distance measures) are commonly used for continuous data. (For descriptions of frequently used methods for combining clusters, see Everitt et al., 2001, pp. 40 & 62, and Norušis, 2010, pp. 372–4).

Cluster analysis is applied following seven steps (Everitt et al., 2001; Milligan, 1996)

1. Selection of entities to cluster.
2. Selection of the variables in the data set on which to group the observations or participants.
3. Standardization of the variables.
4. Selection of a similarity or dissimilarity measure.
5. Selection of the clustering method.
6. Determination of the number of clusters.
7. Replication, interpretation, and testing of the results.

Explanation and Example

The first step in cluster analysis is to select the entities, or observations, to include in the study (Milligan, 1996). Random sampling is not required, unless the researcher wishes to generalize to a larger population. The selected sample should be representative of the cluster structure believed to be present. There are no firm rules for sample size, other than the obvious recommendation to have more observations than variables and resulting clusters, but sufficient observations should be included so that the sample can be subdivided into two groups for the purpose of replication (described below). For example, Csizér & Dörnyei (2005) used a 3% random subsample in their hierarchical cluster analysis and the remainder of the sample in their k means analysis.

The second step in cluster analysis is to define the variables on which participants or observations in the sample are to be grouped. Technically, there are no prescribed mathematical or statistical rules that limit this number, but the more variables used the more complex the results will be, which will make group-based descriptions more difficult as the number of clusters might increase with the use of more variables. Milligan (1996) points to one major caution in terms of variable selection: Only those variables which are believed to increase the discrimination of observations in the data set should be included because the addition of only one or two unnecessary variables can dramatically affect the results.

The third step in cluster analysis is to consider standardizing the variables. Some believe that in order to have unified distances, variables should be standardized. If not, values with larger values will contribute more to the distance measure than the variables with smaller values (Norušis, 2010). However, both Milligan (1996) and Everitt et al. (2001) caution that standardization is not always necessary; if clusters exist in the original variable space, they claim that standardization may hide the clusters. If one decides to standardize the variables, Milligan (pp. 352–3) shows the effects of alternative formulas along with the traditional z score.

The fourth step in cluster analysis is to select the way similarity or distance should be measured among the variables. The researcher should consider the scale of the data: Is it dichotomous, categorical, continuous, or a combination? The selection made in step 5, the clustering method, must also be considered. Different measures are best used with clusters of various shapes (Norušis, 2010). Different statistical programs offer different measures, but the most common distance measures are Euclidean (including Ward's method), correlation, nearest or farthest neighbor, and average linkage.

Figure 1 Screen shot of cluster analysis menus in SPSS™/PASW™

The fifth step in cluster analysis is to decide on the clustering method. The method should be selected to uncover the number of clusters in the data selected, insensitive to error, and available as computer software. Many researchers with continuous data use agglomerative hierarchical techniques with Ward's distance method on a small subset of the data to determine the number of clusters. Then, in step 7 they use a partition/proximity analysis to replicate the number of clusters, thereby strengthening the findings.

Three methods were available in PASW™ (formerly SPSS™) in 2010: hierarchical, *k*-means (a partition/proximity method), and two-step cluster. While all three used continuous data, only the two-step method could analyze categorical data. To run hierarchical clustering in SPSS/PASW, this command sequence is followed: Analyze → Classify → Hierarchical cluster, as illustrated in Figure 1.

The sixth step in cluster analysis is to determine the number of clusters. This decision is somewhat subjective. Researchers familiar with cluster analysis use what are called "stopping rules," a topic beyond the scope of this entry. (See Milligan and Cooper, 1985, for a seminal study.) Norušis (2010, pp. 368–71) recommends looking at the agglomeration schedule and the dendrogram in the SPSS output. A dendrogram is a visual representation of the steps of the clustering procedure. The SPSS/PASW command sequence: Analyze → Classify → Hierarchical cluster → Plots → Dendrogram, generates a dendrogram in the output. An example is shown in Figure 2. The vertical lines show the stages in the analysis in which clusters are formed. Together with the information in the agglomeration schedule, if researchers are using a dissimilarity measure (such as Ward's method), they want to see the stages at which the distances are large to stop cluster formation. The circles in Figure 2 illustrate the researcher's decision to apply a four-cluster solution.

The seventh and last step in cluster analysis involves replicating the clusters, interpreting them, and testing them. Each of these is described below.

4 CLUSTER ANALYSIS

***** HIERARCHICAL CLUSTER ANALYSIS

Figure 2 Illustration of a dendrogram and the subsequent decision about four clusters identified in the data set (SPSS™/PASW™)

Replicating Clusters

Because most cluster techniques will find a cluster solution in a data set, it is necessary to validate a cluster solution. One method for validation is to replicate a cluster solution across different samples of a population, or across different subsets of a data set (e.g., Lorr, 1983; Lorr & Strack, 1994; Milligan, 1996). Milligan (pp. 368–9) describes a number of steps to follow in a replication analysis.

1. Obtain two samples of data. Recall that Csizér & Dörnyei (2005) divided their data set into two subgroups.
2. Cluster analyze the first sample and obtain cluster centroids. The first subgroup undergoes a complete cluster analysis, as was described above. Once the clusters are determined, their centroids are obtained. Researchers often use Ward’s method with the first subgroup, as the centroids it produces have been shown to provide robust “seed points” for the analysis in step 3. Cluster centroids are the center points for each cluster, which are calculated based on the positions of the cluster members, and the center is the point which is the closest to each case within the cluster. In order to do this, first the cluster solution needs to be saved (SPSS command sequence: Analyze → Classify → Hierarchical cluster → Save → Single solution → Number of cluster: 4). Next, the mean values of the cluster variable (clus4_1) are calculated with descriptive statistics and these results are to be fed into a separate SPSS data file (see Figure 3).

	cluster_	var1	var2	var3	var4	QCL_1	var1	var1
1	1	2,35	2,17	3,64	3,68	1		
2	2	2,95	2,78	4,22	4,14	2		
3	3	3,97	3,94	4,54	4,63	3		
4	4	4,42	4,40	4,74	4,77	4		
5								
6								
7								
8								
9

3. Directly cluster analyze the second sample. All decisions regarding selection of variables, standardization, and number of clusters will mirror the analysis of the first subset. Now, however, a partitioning/proximity cluster technique is often used, namely *k*-means analysis (SPSS/PASW command sequence: Analyze → Classify → K-Means cluster). During this process, sample members are put into a predefined number of clusters and the initial cluster centers (“seeds”) are read from an external file (produced in the previous step). The distances between the second sample data points and the centroids obtained from the first sample are determined, and data points from the second sample are assigned to their nearest centroid. Here, all observations are assigned to a cluster. The grouping of the observations or participants into the clusters is done in an iterative way; that is, sample members closest to these predefined centers are assigned to these initial clusters. As a consequence, new centers are obtained (centers are defined based on the positions of the cluster members, and the center is the point which is the closest to each case within the cluster) and sample members are regrouped according to these new centers. The process of *k*-means clustering is repeated until stable cluster centers are obtained; in other words, no changes are detected between two subsequent regroupings in terms of the position of the cluster centers. The cluster memberships of the observations are saved.
4. Compute a measure of agreement between the two clusterings. Two frequently used measures of agreement are Cohen’s kappa and Hubert and Arabie’s corrected Rand index; the level of agreement reflects the stability of the cluster solution.

Interpreting Clusters

Once the clusters have been identified, they need to be interpreted. Similar to naming factors in factor analysis, the subject-matter knowledge of the researcher is indispensable. In order to find out more about the clusters, one-way analyses of variance (ANOVAs) can be run separately for each variable yielding the mean value for each cluster. ANOVA only provides information to describe the cluster groups in a meaningful way and helps to assign label names to the cluster groups. It is important to underscore the point that the ANOVA results should only be used descriptively; interpreting their results as significant is inappropriate because the groups were obtained from their maximum differences on each variable and so results will almost always be significant (Milligan, 1996; Everitt, Landau, & Leese, 2001; Norušis, 2010). In the example used above, cluster 1 was interpreted

as “high level of contact,” cluster 4 as “low level of contact.” Not uncommonly, the clusters in the middle were a bit more difficult to interpret or “name.”

Testing Clusters

Traditional hypothesis testing is another approach for validating the clusters. If a study has dependent variables not included in the cluster analysis, the researcher could run ANOVAs (or another appropriate analysis depending on the variable's scale) in order to find out whether the cluster group membership accounts for meaningful differences (Milligan, 1996; Dörnyei, 2007).

Clyne, Michael

TIM MCNAMARA

Michael Clyne (1939–2010) was an Australian sociolinguist and sociologist of language who worked in the areas of language contact, code switching, bilingualism and multilingualism, immigrant language maintenance and shift, language education, language policy, and the sociolinguistics of the German speech area. He was a passionate advocate of multilingualism.

Clyne's interest in bilingualism and multilingualism dated from the circumstances of his early life. He was born in Melbourne to parents who had recently arrived from Vienna as refugees from Nazism following the *Anschluss*. He grew up in a rather isolated environment amid wartime suspicion of German speakers, even those who were refugees, and directed his passion then and subsequently throughout his childhood to exploring languages and the language phenomena immediately around him—the presence of the various languages (especially German, but also Hungarian, Croatian, and Czech among others) spoken by members of his family and family circle, and the associated experience of bilingualism, and code switching. He recounts a wonderful example of the latter from when he was a boy of five: his mother, asleep in the sun on a deck-chair at home, spoke the following in her sleep: “Das ganze Jahr muß ich waschen ein boy's shirt” (Clyne, 1992a, p. 400).

His academic training began at the University of Melbourne, where he studied a number of Germanic languages: German (one of his mother tongues), Dutch (in which he achieved native-like fluency), Icelandic, and Norwegian. (He later studied Old and Modern Frisian at Utrecht and Swedish at Bonn.) There followed graduate study in Utrecht and Bonn, with a master's thesis on an aspect of historical dialectology. On his return to Australia Clyne was appointed to a junior academic position at the recently established Monash University in Melbourne. As an undergraduate he had come across Einar Haugen's *The Norwegian Language in America* (Haugen, 1953), which he devoured, as it related closely to his family experience; it introduced him to the academic discussion of languages in contact in the context of language maintenance and shift, an interest which came to full flower in his PhD on code switching in German–English bilinguals in Australia and which informed his subsequent career. He spent many years in the German department, before in 1988 taking up a chair in linguistics at Monash, which he held until 2001. His final years of remunerated academic life (2001–4) were spent as a professorial fellow in the School of Languages and Linguistics at the University of Melbourne, his alma mater. In retirement he remained in emeritus and honorary professorial positions at Monash and Melbourne respectively.

Clyne's research on languages in contact, a continuing expression of his experience of his earliest years, took many forms. As a Germanist, spending the first quarter century of his academic career in a German department staffed mostly by literary scholars, he might have been somewhat isolated from developments in linguistics, but had the good fortune to be working at Monash when it established the first linguistics program in Australia, under Göran Hammerström. Other linguist colleagues at Monash included the head of the flourishing Japanese program, the neo-Prague School linguist Jiří Neustupný, and for a time Wilga Rivers in French. Clyne explored aspects of language contact from a number

of linguistic perspectives—lexical, syntactic, processing, typological, and phonological. But perhaps more significant was the range of social contexts in which he explored the issue of language contact, leading to pioneering work in a number of fields. His early paper (Clyne, 1968) on the German spoken by guest workers was a forerunner of studies of immigrant language learning both in Europe and Australia. It was also an early contribution to research on the relation of second language production to processes of pidginization, which was to become a major topic in second language acquisition in the work of applied linguists at UCLA, especially Roger Andersen and John Schumann.

A third area was second language attrition, an interest triggered by awareness of what was happening to elderly Dutch- and German-speaking long-term immigrants to Australia. A fourth area was cross-cultural communication and interlanguage pragmatics: A paper in Clyne (1972) again anticipated much work that was to follow subsequently, including a volume of his own on intercultural communication in the multilingual and multicultural workplace (Clyne 1994). A specific aspect of this work was the question of the generic differences in writing, particularly scholarly writing, across cultures, with particular reference to German and to English, something of which Clyne obviously had direct experience. The final area was language maintenance and shift, the subject of two of his best-known books, *Multilingual Australia* (Clyne, 1982) and *Community Languages: The Australian Experience* (Clyne, 1991). This set a pattern for documenting the fate of immigrant languages in Australia that continued with the analysis of census data until the end of his life, as Australia's demography rapidly changed as a consequence of its diverse refugee intake and its greater orientation to Asia. A later volume (Clyne & Kipp, 2006), for example, provided studies of Somali, Filipino, and Macedonian in Melbourne. Two other books from the "Melbourne era" were well received: *Dynamics of Language Contact* (2003), which used comparative data from migrant languages in Australia to reconceptualize a range of language contact issues, and *Australia's Language Potential* (2005), intended for a more general audience, which raised issues concerning the place of monolingualism and multilingualism in Australian society.

Given Clyne's enduring interest in multilingualism and language contact, it was natural that he should have played a role in policy developments affecting that area. By the early 1970s, a cultural revolution was under way in Australia, triggered by the rapid economic growth and population expansion of the 1950s and 1960s, especially through the vigorous immigration program, and the political protests in the late 1960s arising from Australia's involvement in the Vietnam war. This culminated in 1972 with the election of the Whitlam Labor government, the first nonconservative government for 23 years. One of the features of the radically changed social and political atmosphere in Australia was a policy of multiculturalism to replace the discredited and overtly racist White Australia policy, which only formally came to an end at that time. Clyne was an early advocate of the teaching of the languages of the new immigrant populations in schools (Clyne, 1964), and an advocate of language planning to reflect the new changed multilingual reality of Australia. The high point of this period was the adoption in 1987 of the National Policy on Languages (Lo Bianco, 1987). Clyne became the director of one of the research centers established under the policy, the Language and Society Centre at Monash. Clyne was involved in the establishment and evaluation of a bilingual German–English program in schools, and advocated (by example and by teaching) the raising of children bilingually in families where that was feasible.

Parallel to Clyne's work on language contact and multilingualism in Australia was his contribution to European sociolinguistics, with books on the sociolinguistics of the German-speaking countries (Clyne, 1984), pluricentric languages (Clyne, 1992b), the changing role of German in Europe (Clyne, 1995), and a comparative study of address terms in European languages with colleagues at Melbourne (Clyne, Norrby, & Warren, 2009).

Michael Clyne was honored by the Australian, German, and Austrian governments, and received several prestigious international awards for his scholarship. In retirement he maintained the tireless energy, the curiosity, and the enthusiasm for multilingualism that marked his long career.

COBUILD Project

NICHOLAS GROOM

The COBUILD project was a partnership between Collins publishers (later HarperCollins) and the University of Birmingham, UK, which was established in 1980 and lasted for two decades. The aim of the project was to develop and publish a range of English language learning and teaching materials based exclusively on the analysis of computerized corpora of attested spoken and written texts collected from a variety of British, North American, and Antipodean sources (hence the acronymic project title Collins Birmingham University International Language Database). Often cited as an exemplar of genuinely successful and mutually beneficial collaboration between academic and commercial interests in applied linguistics, the COBUILD project is widely acknowledged to have had a major impact on the English as a second language (ESL) publishing industry, and on the design and compilation of monolingual learners' dictionaries in particular. Research associated with the COBUILD project has also made important contributions to linguistic theory, particularly through its close association with cutting-edge developments in corpus linguistics.

The COBUILD project was led from its inception by John Sinclair, then professor of modern English language at the University of Birmingham, UK. Sinclair and his associates at Birmingham had been developing computer-assisted approaches to the study of lexis in electronically stored collections of authentic language data since the mid-1960s (see e.g. Sinclair, 1966; Sinclair, Jones, & Daley, 2004), and it was the promise shown by this early work, together with the rapid advances in computer and document scanning technologies that occurred during the 1980s, that emboldened Collins to fund the COBUILD project as a commercial publishing venture.

Sinclair used this funding to set up and maintain a team of corpus compilers, computer programmers, and lexicographers who worked full time on the COBUILD project. The first published output of this team, the *Collins COBUILD English Dictionary* (CCED), appeared in 1987. This monolingual learner's dictionary broke entirely new ground in pedagogic lexicography through its extensive use of computer corpus data. Of particular note was the use of frequency lists to determine not only which words would be included in the dictionary (only the most frequent words were granted headword status), but also how the different senses of polysemous words would be ordered (see Figure 1). For example, CCED presents *back* as an adverb and preposition first, and as a noun referring to a part of the human body second, on the grounds that this ordering reflects the relative frequency of these two forms and meanings in native-speaker usage as represented by the corpus. The pedagogic rationale for this approach is that it prioritizes words and phrases that learners of English are most likely to encounter, and which express the meanings that they are most likely to want to express for themselves.

Corpus data were also used as the exclusive source of citation material in CCED (concocted examples were not allowed), and as the basis for additional information about the typical collocations and usage patterns associated with each headword. Some of this information was presented (in abbreviated form) in an additional column running parallel to the main text for each entry. Other such information was integrated into the wording of the definition itself. The CCED definition style was also highly innovative in that it used full sentences instead of the terse, nominalized style found in virtually all other dictionaries.

baby boom

One of the hallmarks of the COBUILD project throughout its lifespan was its emphasis on building and using very large corpora. The first edition of CCED was based on a corpus of 20 million words. By the publication of the second edition (1995), this corpus had grown to 200 million words, and had become known as The Bank of English. The Bank of English has continued to expand with each subsequent edition of CCED, and the current version of the corpus stands at around 2 billion words. (The version currently held at Birmingham for academic research purposes is a modest 450 million words in comparison.) The main argument for using large corpora is that most words occur very rarely in authentic language data, and a large corpus is thus required in order to obtain enough examples of a given word to form the basis for valid generalizations to be made about it.

In addition to dictionary publishing, the COBUILD project produced a wide range of other ESL learning and teaching resources, grammar reference books, and usage guides. Of these, the most innovative and influential (if not the most commercially successful) are the *COBUILD English Course* (Willis and Willis, 1988) and the prizewinning *Grammar Patterns* series (Francis, Manning, & Hunston, 1996, 1998). The former is widely recognized as the most thoroughgoing implementation of a lexical syllabus yet attempted by a commercial ESL coursebook series, while the latter is noteworthy for its detailed presentation of hundreds of verb, noun, and adjective complementation patterns, and its systematic grouping of these patterns into semantically related groups.

When the COBUILD project drew to a close, the lexicographic and computational work that had previously been done at Birmingham shifted to the HarperCollins offices in Glasgow, Scotland, where it continues to the present. Although the COBUILD project itself no longer exists, HarperCollins continues to use the COBUILD name in its publications, and the COBUILD brand remains one of the best known and most respected in the ESL publishing industry. The academic legacy of the COBUILD project also remains strong in applied linguistics, and is most clearly manifested in the growing popularity of theories such as pattern grammar (Hunston and Francis, 1999) and the 'idiom' and 'open choice' principles (Sinclair, 1991). These theories are a direct product of the computational corpus research that formed the core activity of the COBUILD enterprise, and offer a compelling critique of the traditional distinction between syntax and lexis, and the prioritizing of the former over the latter in much mainstream linguistics.

Code Mixing

ELENA NICOLADIS

“Code mixing” refers to a multilingual’s or a bilingual’s use of two or more languages in a single unit of discourse, such as a word, an utterance, or a conversation (see, e.g., Genesee, Paradis, & Crago, 2004). As “code mixing” is sometimes used exclusively to refer to children’s productions, this entry focuses exclusively on children. An example of code mixing could be the utterance *I like courir* from a French–English bilingual, with the French verb root *courir* meaning ‘to run’ in an otherwise English utterance. Some researchers use the term “code mixing” contrastively with “code switching” (see, e.g., Genesee, 1989; compare Meisel, 1994). “Code switching” implies a deliberate although not necessarily conscious alternation of languages. Researchers studying bilingual children’s use of their two languages have often opted for the term “code mixing” so as to remain uncommitted as to whether children’s alternation of languages is deliberate or not. When children are of preschool age (i.e., between approximately 1 and 5 years of age), researchers have generally opted to remain neutral as to whether their alternation of language is deliberate. This article will therefore focus on preschool bilingual children’s code mixing.

In order to identify some functions of preschool children’s code mixing, it can be useful to identify the functions of code switching in adult bilinguals. Researchers are in general agreement that code switching serves a large variety of functions, including: not knowing a word or linguistic construction in the target language (e.g., Li & Tse, 2002), providing the right word to express a concept exactly (e.g., Poplack & Sankoff, 1988), expressing a sense of identity or power (e.g., Poplack, 1987). Researchers have also noticed that adult bilinguals’ code switching is grammatically constrained, often resulting in utterances that would be grammatical in both languages (e.g., Poplack, 1980) or in at least one language (e.g., Myers-Scotton, 1993).

In contrast to these adult functions, some of the earliest studies of bilingual children interpreted code mixing as a sign of having confused the two languages as a single linguistic system (e.g., Leopold, 1949). Since then, many studies have shown that bilingual children can differentiate their languages very early in development (e.g., Deuchar & Quay, 1999; see review in Genesee & Nicoladis, 2007). Researchers have generally reached the consensus that children’s code mixing is more accurately evidence of their creative and flexible use of (a) limited linguistic resources and (b) the availability of choices in how to express their message. Children’s code mixing may then take on some of the same functions as adult code switching even in the preschool years.

When children are in the one-word stage, they code mix by changing languages between utterances, resulting in inter-utterance code mixing. Code mixing can be identified as the inappropriate language choice for the interlocutor, such as using a Spanish word when addressing an English-speaking adult (e.g., Genesee, Nicoladis, & Paradis, 1995). When bilingual children are in the one-word stage and their productive vocabulary totals around 50 to 100 words or less, one of the primary reasons for code mixing seems to be to refer to a concept that the child can label in only one language. For example, a case study with a Portuguese–English bilingual child showed that about 90% of his inter-utterance code mixing could be attributed to not knowing a word in the language of the interlocutor (Nicoladis & Secco, 2000; see also Genesee, Paradis, & Wolf, 1995). As children get older,

2 CODE MIXING

one of the functions of code mixing is still undoubtedly to fill a lexical or conceptual gap. Bilingual children between the ages of 2 and 4 years generally code mix more when trying to speak their weaker language than when trying to speak their stronger language (Genesee, Nicoladis, & Paradis, 1995; Köppe & Meisel, 1995; Nicoladis & Genesee, 1997). Also, as children get older, the grammatical complexity of their code mixing may increase, particularly in their stronger language (e.g., Bernardini & Schlyter, 2004). Code mixing may allow children to convey concepts in their weaker language that they simply do not have the grammatical capacity to express in that language (see, for example, Gawlitzek-Maiwald & Tracy, 1996).

When bilingual children reach the two-word stage (i.e., when they start to put two different words together in a single utterance), they can produce their first instances of intra-utterance code mixing, or code mixing within a single utterance (Genesee, Nicoladis, & Paradis, 1995). For example, a Spanish–English bilingual might say *Dónde doggie?* ‘Where doggie?’ Researchers have shown that, from the age of 2 years on, bilingual children’s code mixing shows roughly the same patterns of grammatical constraints as adults’ code switching (e.g., Meisel, 1994; Köppe & Meisel, 1995; Allen, Genesee, Fish, & Crago, 2002; Paradis, Nicoladis, & Genesee, 2000). For example, bilingual children show a tendency to mix a single word, often a noun, into an utterance that is otherwise in the other language (e.g., Lanza, 1992; Meisel, 1994). Where more than a single word is code mixed, children often use a large enough chunk of language so as not to violate the grammar of either of their languages (e.g., Paradis et al., 2000). Paradis et al. (2000) cite examples of French–English bilingual children’s code mixes between English strong subject pronouns and French verbs, as in *I vas taxi* ‘I go taxi’ (p. 257). French subject pronouns are clitics and therefore much less separable from inflected verbs. So, by mixing at the point of the subject pronoun and verb, children violate neither French nor English grammar.

It is not yet clear when in the course of development children’s code mixing becomes a reflection of identity or power issues, but it is clear that sociolinguistic factors affect even preschool children’s code mixing. For example, the rate of code switching used by adults varies across communities (e.g., Poplack, 1987). Children’s rate of code mixing can resemble that of adults in the community from the age of 2 to 3 years (e.g., Tabouret-Keller, 1963; Nicoladis & Genesee, 1997). It is possible that the resemblance in rate has to do with children’s imitation of the adults and older children in their community. Similarly, part of the reason that children’s code mixing comes to resemble adults’ code switching may be that adults systematically socialize children in how to use their two languages. For example, Lanza (1992) argued that a Norwegian–English 2-year-old bilingual code mixed less with her English-speaking mother than with her Norwegian-speaking father because the mother systematically responded to the child’s use of Norwegian as if she did not understand it.

One recent study is suggestive that bilingual children’s code mixing and language use more generally may be related to the majority versus minority language status in the community. Paradis and Nicoladis (2007) examined the language use of 3- to 5-year-old French–English bilinguals who were growing up in a context in which English was the majority language. They observed that the children were more likely to code mix when speaking with a French interlocutor than with an English interlocutor. Furthermore, the French-dominant children could speak primarily one language in both an English and French context while the English-dominant children were more likely to code mix in the French context compared to the English context. Paradis and Nicoladis (2007) argue that these results reflect the majority status of English in the community in which the children were growing up, but it is not clear if the children themselves were sensitive to the majority-language status of English. Paradis and Nicoladis (2007) point out that the children’s behavior could be a reflection of their parents’ behavior, of their parents’ socialization techniques, or even of the number of bilinguals the children had met.

In sum, when bilingual children first start speaking, they often code mix to fill lexical gaps, as adult bilinguals sometimes do. Code mixing to fill lexical gaps remains a function of code mixing, even as children get older. As soon as bilingual children are old enough to use grammatical constructions, their code mixing is largely grammatically constrained, much as adults' code switching is. Within the preschool years, there is some evidence that sociolinguistic factors affect children's code mixing, but it is not yet clear whether children themselves are code mixing to express their identity or power relations.

Code Switching

MARGARET DEUCHAR

Introduction

Code switching (CS) is an activity which may be observed in the speech (or writing) of bilinguals who go back and forth between their two languages in the same conversation. Please note that Spanish words are underlined, English words are shown in normal style, and **Welsh** words are shown in bold. Key to glosses: PL = plural, SG = singular, M = masculine, PRON = pronoun, DET = determiner, PRT = particle, NEG = negative/negative particle, DEM = demonstrative, DAT = dative, ACC = accusative, INF = nonfinite, PRES = present, IMP = imperfect tense, FUT = future tense, 1SG/1PL = 1st person singular/plural, 2SG/PL = 2nd person singular/plural, and 3SG/3PL = 3rd person singular/plural. Examples (1)–(6) illustrate code switching from recorded conversations between Spanish-English, Welsh-English, and Welsh-Spanish bilinguals. The data were collected as part of the research program of the ESRC Centre for Research on Bilingualism (www.bilingualism.bangor.ac.uk) and with funding from the AHRC for a grant awarded to the author for a project on “Code switching and convergence in Welsh: A universal versus a typological approach” (for the Welsh-English data see <http://talkbank.org/data/BilingBank/Bangor/>).

- (1) él siempre me da cumplido-s así
he always me.DAT.1SG give.PRES.3SG compliment-PL like_this
'he always gives me compliments like this'
so I said to him, “talk to me in two more years” (Sastre 9, see
<http://www.talkbank.org/data/Bilingbank/Bangor/>)
- (2) pero hasta ahora because él nada más tiene que quince
but until now because he nothing more have.PRES.3SG than fifteen
añ-it-o-s ya para dieciséis next month
year-DIM-M-PL already for sixteen next month (Sastre 9, see
<http://www.talkbank.org/data/Bilingbank/Bangor/>)
'but until now, since he isn't more than fifteen years old, turning sixteen next month'.

'I'll do biotechnology because I can't register for two things'.

2 CODE SWITCHING

A more accessible term for code switching might be *language switching*, but as Gardner-Chloros (2009, p. 11) explains in her textbook on the topic “Nowadays *code* is understood as a neutral umbrella term for languages, dialects, styles/registers, etc.” As for how the term *switching* is used, we can illustrate this with reference to example (3). Here we can see that there has been a language change or switch between the Welsh word *yna* (‘there’) and the English word *quick*. But in the code switching literature linguists tend to use the term “switch” to refer not to the point at which there is a switch between words from two languages, but to a sequence of words representing a change from the previous language. So in (3), whereas the first switch point occurs between the Welsh word *yna* (‘there’) and the English word *quick*, linguists would normally refer to the sequence of English words *quick fixes* as constituting the switch.

While the notion of switch has mostly been taken for granted in the literature, it is not as obvious as one might think. In example (3) there is in fact a switch back to Welsh after *quick fixes*, so the question arises whether the Welsh sequence *i bob dim* (‘for everything’) should be counted as a switch as well. In practice linguists tend to count as a switch a word or sequence of words in a different language from the language in which the utterance begins. However, for a discussion of why a linear approach of this kind might be problematic, see Deuchar, Muysken, and Wang (2007, pp. 309–10).

As shown in examples (1)–(4), switches may consist of one word only, as in, for example, *because* in (2) or *inscribwr* (‘to register’) in (4), or more than one word, as in *quick fixes* in (3). Single-word switches raise a particular problem for CS researchers, as they have to decide which words from another language are in fact borrowings established some time ago as adoptions into the recipient language, or whether they are switches into another language. Of course switches can be used only by bilinguals who speak more than one language, so we can be fairly sure that words used by monolinguals will be borrowings. For example, the word *restaurant* is an English word borrowed from French in the 19th century and is used by English-speakers who speak no French. Sometimes, though, it is hard to find monolingual speakers of a language to help identify which words are borrowings. This is the case with Welsh, whose speakers live in a society dominated by English, and who generally become bilingual in both Welsh and English from an early age. To help us solve this practical and theoretical problem in our research at Bangor on Welsh-English CS, we started by considering English words that we found in a respected Welsh dictionary (Thomas, 1950–2002) to be borrowings, and other words to be switches. This meant that we counted examples like *sbwnjo* (‘sponge’) in (5) as a borrowing and therefore as a Welsh word, instead of considering it a switch into English. On the other hand, we counted examples like *exfoliate-io* (‘exfoliate’) as switches because they are not (yet) in the dictionary. Since switches often become borrowings over time, future editions of the dictionary may include this and other similar words. Dictionary makers have to make what may be fairly arbitrary, practical decisions about what to include in their dictionaries, and they are not helped by the fact that there is considerable debate among researchers, who have debated for more than half a century about how to identify a borrowing rather than a switch (see, e.g., Haugen, 1950; Weinreich, 1953; Pfaff, 1979; Poplack & Sankoff, 1984; Heath, 1989; Myers-Scotton, 1992; Poplack & Meechan, 1998).

Poplack (1980) suggests that a code switch may be partially but not fully integrated into the recipient language, that is, the language into which it is switched. Borrowings or loanwords, however, may be fully integrated: “Established loanwords assume the morphological, syntactic and often, phonological, identity of the recipient language” (Poplack, 2004, p. 590). According to Sankoff (2001), significant progress was made by Poplack and Meechan (1998) in developing a quantitative method for distinguishing between switches and borrowings. They compared “lone other-language items” (i.e., words whose status as a switch or borrowing was unclear) with words of the same grammatical category in the

recipient language in which these other-language items were being used. Applying this method, Eze (1998), for example, concluded that English-origin verbs inserted into Igbo discourse behave like Igbo verbs phonologically, morphologically, and syntactically and should therefore be considered borrowings (Igbo is a language spoken in Nigeria). Stammers (2010), however, argues that some differences between English-origin and Igbo verbs have been underplayed and that the evidence for a clear distinction between borrowing and switching may have been overinterpreted. In his own study of the integration of English verbs into Welsh, Stammers (2010) finds a clear relation between the frequency of use of those English verbs and their level of integration. So as a rough guide, highly frequent other-language items are good candidates for borrowings, while low frequency items may be viewed as switches, though the dividing line between the two categories is not always clear.

We now turn to what motivates researchers working on CS, or what questions they are trying to answer. Two of the most common research questions pursued by those working on code switching are the following:

1. Are there rules governing CS like the rules of grammar of a single language?
2. Why do bilinguals code switch?

In answer to the second question, Bullock and Toribio (2009) suggest that people may use CS as a marker of their identity, to confer status, or to achieve particular communicative goals. Gumperz (1982) wrote a seminal article in which he argued that the functions of CS included quoting the speech of others, identifying the person being addressed, repeating the same message for emphasis, and adding more details to the main message. Gumperz's work inspired much in the framework of conversational analysis, where some researchers argued for the importance of CS in structuring conversations (see Auer, 1984, 1998; Gardner-Chloros, 2009, chap. 4). Turning to the relation between CS and identity, Chen (2008) argued that distinctive CS styles are used by returning versus local Cantonese-English bilinguals in Hong Kong, and that these express contrasting identities. Sayahi (2004, p. 377) argues that "code-switching by Spanish-English bilinguals in New York goes beyond the immediate conversational functions to help forge a hybrid social identity unique to this group."

It could be argued that in order to discover why bilinguals switch, we first need to know where it is possible for them to switch, or at which points in their speech they have a choice between staying in the same language and switching to another. This takes us to the first question above, "Are there rules governing CS like the rules of grammar of a single language?" In order to address this question we need to draw a distinction between switching within the clause ("*intraclausal* switching") and switching between clauses ("*interclausal* switching"). Intraclausal switching is illustrated by example (5), which can be broken down into clauses as shown, with the beginnings and ends of clauses marked by square brackets:

- (5) [mae nhw (y)n exfoliate-io chdi gynta] [ac yn sbwnjo chi
be.PRES.3PL they PROG exfoliate-INF you first and PRT sponge-INF you
drosodd gynta]
over first
'they exfoliate you first, and sponge you over first' (Fusser 29, see
<http://www.talkbank.org/data/Bilingbank/Bangor/>)

This example is divided above into two coordinated clauses of which the first contains intraclausal switching in the form of *exfoliate*. Interclausal switching, on the other hand, can be illustrated by example (1) above. This is repeated below with the clause boundaries shown by square brackets:

4 CODE SWITCHING

- (1) [él siempre me da cumplido-s así]
he always me.DAT.1SG give.PRES.3SG compliment-PL like_this
'he always gives me compliments like this'
[so I said to him, ["talk to me in two more years"]] (Sastre 9, see
<http://www.talkbank.org/data/Bilingbank/Bangor/>)

Some switches can be classified as both intraclausal and interclausal, as in example (6):

- (6) [I wonder [pryd o'n i yma] then]
I wonder when be.IMP.1SG I here then
'I wonder when I was here then'

In this example the switched material is in Welsh (*pryd o'n i yma*) and is intraclausal in that it is a subordinate clause within the clause [*I wonder . . . then*]. At the same time, because it is a complete clause in itself, it can be considered interclausal. This kind of example illustrates that no data analysis is simple!

The terms *intraclausal* and *interclausal* are actually found in the literature on CS less commonly than the alternative terms *intrasentential* and *intersentential*. However, this author prefers the former terms since the term *intrasentential* can be ambiguous between *intraclausal* and *interclausal* when the latter refers to switching between two clauses in the same sentence. We can illustrate this with the famous title of the article by Poplack (1980) shown in (7) with square brackets indicating the separate clauses:

- (7) [Sometimes I'll start a sentence in Spanish] [*y termino en español*].
'Sometimes I'll start a sentence in Spanish and end in Spanish'.

Some researchers would describe the switch from the English of the first clause to the Spanish of the second clause as *intrasentential* because it occurs within the sentence, while others would describe this as *intersentential* switching because a clause is a kind of minimal sentence. This second group would probably reserve the term *intrasentential* for the kind of switches that occur in examples (2)–(4) above. So to avoid the ambiguity of the term *intrasentential* it is arguably preferable to use the terms *intraclausal* and *interclausal*.

To return to our question of where code switching is allowed to take place, there seem to be few restrictions on it occurring between coordinated clauses or sentences. Whether speakers take up the option to do interclausal switching is another question, and may vary from community to community. Restrictions do seem to apply, however, to where intraclausal CS can occur, and our focus will be on this type of switching in the rest of the entry. Researchers generally agree that there are restrictions, but where they do not agree is on the question of what the best theoretical account of these restrictions is.

A particularly interesting question for researchers investigating intraclausal CS is what happens when material from two languages is combined in a sequence for which the grammatical rules in the two languages would be different. For example, it is well known that the order of words within the noun phrases of different languages varies from language to language. In some languages, like French, the adjective normally follows the noun whereas in others, like English, the adjective precedes the noun. So whereas in the English phrase *red wine* the adjective *red* comes before the noun *wine*, the order is the opposite in the French equivalent, *vin rouge*, with the noun *vin* ('wine') coming first and the adjective *rouge* ('red') coming second. In corpus data collected by our team at Bangor, we have two pairs of languages showing the same contrast, Welsh-English and Spanish-English. Welsh and Spanish behave like French in that the adjective normally comes after the noun, in

contrast to the order found in English. There are currently two contrasting approaches to dealing with questions like this regarding the rules for CS. These will be called the symmetric and the asymmetric approaches here. The asymmetric approach is associated with the notion of a matrix language (see Myers-Scotton, 2002, 2009) and assumes that one of the two languages spoken by a bilingual provides the grammatical rules for a given clause, with the other language material being slotted in. The symmetric approach, better known as minimalism (MacSwan, 2009) does not assume priority for any one language but allows for lexical items to be drawn from either language and for their features to determine the possibility of their combination. The two contrasting approaches can be illustrated with reference to example (8):

- (8) **maen nhw (y)n bryderus am roid y bid cyntaf i_mewn**
 be.PRES.3PL they PRT anxious about put.INF DET bid first in
 'they are anxious about putting the first bid in' (Stammers 6, see
<http://www.talkbank.org/data/Bilingbank/Bangor/>)

According to one version of the minimalism approach (see Cantone & MacSwan, 2009) the relative order of the noun and the adjective in (8) will be determined by the normal order in the language of the adjective, *cyntaf*, which in this case comes from Welsh. In Welsh the noun is normally followed by the adjective, as happens here, where the noun *bid* is followed by the adjective *cyntaf*. In relation to this example the contrasting matrix language approach actually makes the same prediction, though for different reasons. In the matrix language approach the noun-adjective order should follow the language of the grammatical frame as determined by the language of the finite verb and the relative order of the verb and the subject. In this example the finite verb *maen* is Welsh and the verb precedes the subject as is normal in Welsh. Thus the noun is expected to be followed by the adjective as is normal in Welsh.

We now turn to two examples, (9) and (10), for which the two theoretical approaches make different predictions:

- (9) **oedd gynnon ni ystafell yn Plas yn Dref, ystafell brilliant**
 be.3S.IMP with-US PRON.3S room in Plas yn Dref room brilliant
 'we had a room in Plas yn Dref, a brilliant room' (Deuchar, 2006, p. 1994)
- (10) **tibod y y raw peth (y)ma (fe)lly de**
 know.2S DET DET raw thing here thus TAG
 'so you know the raw thing don't you' (Robert 3, see
<http://www.talkbank.org/data/Bilingbank/Bangor/>)

In (9) the language of the adjective, *brilliant*, is English, so the symmetric (minimalism) approach would predict that the relative order of the Welsh noun *ystafell* ('room') and adjective *brilliant* would be as in English. The asymmetric (matrix language) approach, on the other hand, would note that the grammatical frame of the clause is Welsh and so expect the noun-adjective order to be in Welsh. In this case the minimalism approach makes the wrong prediction and the matrix language approach the right one.

The tables are turned when we look at (10), however. Here the adjective-noun order is as the minimalism approach would predict: it follows English, the language of the adjective *raw*. Although the grammatical frame is Welsh the adjective (*raw*) does not follow the noun (*peth*) as is normal in Welsh. The matrix language approach thus makes the incorrect prediction for this example.

Table 1 Examples of mixed noun/adjective constructions showing (in)compatibility with competing theoretical approaches

<i>Example</i>	<i>Gloss</i>	<i>Grammatical frame of rest of clause</i>	<i>Compatible with minimalism approach?</i>	<i>Compatible with matrix language approach?</i>
y bid cyntaf	‘the first bid’	Welsh	yes	yes
ystafell brilliant	‘brilliant room’	Welsh	no	yes
y raw peth	‘the raw thing’	Welsh	yes	no

Table 1 shows which of the examples so far are compatible with each approach. If we were to award a point for each occurrence of “yes” in the above table we would see that there is a “draw” between the two theoretical approaches, with each approach receiving two points for compatibility with two of the three examples, and each being incompatible with one (different) example. But no conclusion can be drawn on the basis of only three examples (particularly since the order in *y raw peth* seems not to be preferred by speakers) and this interesting issue awaits further research. Phrases with the noun and adjective in different languages are in fact fairly rare where the normal order in the two languages is different, and this may be for reasons of congruence (see Deuchar, 2005), according to which switching between two categories may be inhibited where the relative order of words in these two categories differs in the two languages. However, future experimental work may be able to obtain more data consisting of sequences of nouns and adjectives like those shown in Table 1. (See Gullberg, Indefrey, & Muysken, 2009, for some ideas regarding possible experimental techniques.)

The two approaches outlined above involve formulating rules for CS and then checking with data to see if the rules are followed. The two approaches have in common that they claim universality, or that their predictions apply to all data. Muysken (2000), however, presents a different, typological approach which instead of making universal predictions about rules to be followed, describes three possible patterns of CS based on consideration of the data. This typological approach makes few assumptions about the data in advance, except that they will follow one of the three patterns. It also is broader in that it applies to interclausal as well as intraclausal CS, whereas the other approaches apply only to intraclausal CS. Although Muysken’s approach is not concerned directly with question (1) above about the “rules” of CS, it does allow for the possibility of relating different CS patterns to social factors, like the status of the languages in the communities, or the proficiency of the speakers.

This entry has focused on CS from the standpoint of linguistics, although other approaches are possible. The issue of whether there are “rules” of CS has been addressed and two contrasting approaches which assume there are rules have been outlined. A third approach has also been mentioned which prefers the notion of various patterns to rules. All the approaches agree, however, that there are limits on the way material from different languages can be combined in the same conversation. Further research should help to indicate exactly what these limits are, and how the characteristics of the speaker or the community they live in can make a difference to the possibilities of language combination.

The author would like to acknowledge the following collaborators for their assistance in collecting, transcribing, and analyzing the data: Fraibet Aveledo, Diana Carter, Peredur Davies, Marika Fusser, Jon Herring, Siân Lloyd, Esther Nuñez Villanueva, M. Carmen Parafita Couto, Myfyr Prys, Elen Robert and Jonathan Stammers. Thanks also to Gary Smith and Jonathan Stammers for assistance with the sound clips.

Cognates

RENA HELMS-PARK AND VEDRAN DRONJIC

Defining Cognates

Cognates can be defined in multiple ways depending on one's research or pedagogical focus. In historical linguistics, the approach is etymological; cognates are words in one or more languages descended from a common ancestor, either directly (for example, English *tongue* and Irish *teanga*, which are descendants of a Proto-Indo-European word containing the hypothesized root **dinghwa-*) or through borrowing (as is the case with the English and Slovene words *robot*, both originating in Czech). Cognates can exist within one language, as with *cap*, *chief*, *chef*, and *head* (the first being derived from the Latin word *caput* 'head', *chief* and *chef* being borrowed from French at different times in the history of English, and *head* being the direct Germanic development from Proto-Indo-European). Due to semantic drift, cognates can have slightly or significantly different meanings. For instance, Romanian *lume* 'world' and Catalan *llum* 'light' are both descended from Latin *lumen* 'light', yet their different meanings render them *false friends*. False friends should be distinguished from *false cognates*, which are pairs that are formally similar but derived from different sources. At first encounter, a German-speaking learner of Swedish might be tempted to believe that Swedish *öl* is cognate with German *Öl* 'oil', whereas it actually means "beer" (cf. English *ale*). Both *öl* and *ale* are descended from the hypothesized Proto-Germanic root **alut-*, while German *Öl* and its Swedish cognate *olja* 'oil' can both be traced back to Latin *oleum* 'oil'.

From a psycholinguistic viewpoint, the emphasis when defining cognates is generally on degrees of formal similarity, either in auditory (spoken) or visual (orthographic) modality, since this has bearing on the recognizability of cognates. On a cline of recognizability, while English *father* is close to Danish *fader* (older form), it is less so to Danish *far* (newer form); and the connection between Irish *athair* and English *father* seems even more opaque. Phonetic overlap at the beginning of the word appears to increase recognizability (as in Marslen-Wilson's cohort model, 1987). Similarly, while English *ass* might be recognized as a cognate of Italian *asino* 'donkey', neither of these might seem related to French *âne*, 'donkey'. Likewise, orthography might obscure cognates which are easy to recognize in their spoken form (e.g., Argentine Spanish *lluvia* /'fuβja/ and Northern European Portuguese *chuva* /'fuβe/ 'rain'). Conversely, the cognate status of a pair of words may sometimes be obscured by phonology and in spite of similar spelling. For instance, while the connection between Danish *stjerne* and (Central) Swedish *stjärna* ('star') is relatively easy to recognize in writing, the spoken forms of these words, /'sdjæɣnə/ and /'hjæ:ɳɳa/, respectively, are much harder to recognize as cognates. Clearly, all of the above factors must be considered by researchers when designing experiments and by educators when dealing with cognates in lexical syllabi, as they will inevitably have an effect on processing.

In second language acquisition and processing research the definition will likely be more psycholinguistic than etymological or historical, that is, COGNATE = [+ FORM OVERLAP, + MEANING OVERLAP]; FALSE FRIEND = [+ FORM OVERLAP, – MEANING OVERLAP]. However, as a result, we end up with an anomalous situation where etymologically false

cognates, such as Mandarin *māma* 妈妈 ‘mother’ and Serbo-Croatian *mama* ‘mommy’, in theory could well be represented and processed in bilingual brains in a cognate-like way, while etymologically true cognates such as Italian *asino* and French *âne* ‘donkey’ could fail to register as cognates among linguistically naïve learners. Crosslinguistic homographs, such as Spanish *burro* ‘donkey’ and Italian *burro* ‘butter’, can be particularly misleading to learners when initially encountered.

For the above reasons, “cognate” is an ambiguous label in applied linguistics unless its definition is tailored to a specific research or pedagogical context. For example, in order to constrain the definition of cognates, Roberts and Deslauriers (1999) compared pairs of L1 and L2 phonemes for similarity in features, calculated their phonemic distance, and required cognates to have at least 70% feature overlap. Kondrak (2003) recommended using a special algorithm centering on “feature salience” on the grounds that some phonetic features are more important than others. Likewise, to assess visual (orthographic) similarities between pairs of cognates in the same script, there are measures of graphemic distance in the literature (see Gooskens & van Bezooijen, 2006).

Cognates are of interest to applied linguists because of their obvious potential to influence second language learning and processing, for instance by facilitating word recognition and acquisition. Or, because of the easier burden of lexical acquisition, other aspects of L2 learning can be accelerated. In cases when two genetically related languages are very similar typologically and lexically, the number of cognates can be so large as to make possible various degrees of communication between speakers of different languages (e.g., Swedish, Norwegian, Danish; Macedonian, Bulgarian, Serbo-Croatian; Hindi, Marathi, Gujarati; Tamil, Malayalam, Kannada; Spanish, Portuguese, Galician; Zulu, Xhosa, Swati). This sort of facilitation has implications for lexical testing, as discussed below.

Research on Cognate Facilitation

Research involving bilinguals indicates that cognates are recognized, learned, and translated faster than non-cognates (Kroll & Stewart, 1994; Lotto & de Groot, 1998), especially when these items are high frequency in the L1 and low frequency in the L2 (Dijkstra, Grainger, & van Heuven, 1999). Among bilinguals, cognates are less prone to attrition than non-cognates (de Groot & Keijzer, 2000) and less vulnerable to temporary breakdowns of the lexical retrieval mechanism such as tip-of-the-tongue states (Gollan & Acenas, 2004). However, apart from facilitating acquisition and processing, cognate status can also increase the likelihood of L1-to-L2 phonetic transfer in word production (Patterson & Goldrick, 2008).

In psycholinguistics, priming is a popular research tool that has been widely used to address questions about cognate representation and processing. Most of the early priming research on cognates used overt visual-visual priming (i.e., priming without masking). Those studies which used long stimulus-onset asynchronies (SOAs) (over 300 ms) found facilitation with cognate translation equivalents (Gerard & Scarborough, 1989) but none with non-cognate translation equivalents (Cristoffanini, Kirsner, & Milech, 1986). Note that short SOAs facilitate both form and semantic priming, thereby favoring both cognates and non-cognate translation equivalents, while long SOAs generally facilitate form priming but not semantic priming (since semantic activation is short-lived), thereby favoring only cognates (e.g., de Groot & Nas, 1991).

Whereas nonmasked (overt) priming is susceptible to episodic and strategic processing effects, *masked priming* eliminates these effects since the participant is typically unaware of seeing the prime. Using masked Spanish–English and English–Spanish priming, Davis et al. (2010) found that cognates indeed prime each other (just as words prime themselves). There were similar amounts of priming for equilinguals, Spanish-dominant bilinguals, and

English-dominant bilinguals. The magnitude of priming effects was the same for cognates with differing degrees of orthographic overlap (e.g., *clear*—*claro*; *tower*—*torre*) and in either direction (L1–L2 and L2–L1). However, de Groot and Nas (1991), using both masked and overt priming, found that while both cognate and non-cognate primes accelerated lexical decisions, only cognates displayed associate priming across languages: English *baker* primed Dutch *brood* ‘bread’ (forms related), but English *blanket* did not prime Dutch *laken* ‘sheet’ (forms unrelated). Van Hell and Dijkstra’s (2002) study of Dutch–English–French trilinguals residing in the L1 (Dutch) environment reported English-to-Dutch and French-to-Dutch cognate facilitation, with the latter only observed in participants with sufficient levels of proficiency in French; in general, when one language is considerably weaker than the other, cognate facilitation may not be observed in the L2-to-L1 direction, while it is likely to be observed in the L1-to-L2 direction.

Recently, cognates have also been the focus of studies on nonfluent aphasia, some of which demonstrate that cognates are less vulnerable to loss in cases of brain damage (e.g., Detry, Pillon, & de Partz, 2005). Other studies hypothesize that treatment consisting of picture-naming in one language facilitates naming of cognate equivalents in the other. The results here are often ambiguous (for more on this, see Costa, Santesteban, & Caño, 2005); unidirectional (i.e., cognate facilitation in the L2 but not the L1) (Roberts & Deslauriers, 1999); or without evidence of positive language transfer, as in Meinzer, Obleser, Flaisch, Eulitz, and Rockstroh’s (2007) study of a French–German balanced bilingual, who, after a stroke, received successful language therapy only in German but displayed no transfer to French in language tests or fMRI scans.

Cognate Facilitation: Models

One explanation for cognate facilitation is that cognate pairs share a representation, making any form differences between the two items similar to those between morphologically linked words within a language (Lotto & de Groot, 1998; Sánchez-Casas & García-Albea, 2005). Non-cognates, on the other hand, have language-specific representations in the bilingual lexicon. Thus, when a non-cognate L2 word is learned, a new lexical entry must be created, while an L2 cognate simply requires modifications to the entry of its L1 counterpart.

Another explanation for the quicker acquisition of cognates centers on the form overlap between two separate (language-specific) representations of L1–L2 cognate pairs. First, less form-related learning is required. Second, a lexical stimulus in one language helps the activation and retrieval of its cognate. In addition, as Jiang (2000) suggests, during the word-association stage of L2 lexical acquisition (see Kroll & Stewart, 1994), L1 lemma mediation prevails, whereby the learner ascribes an L1 lemma to an L2 phonological word structure. In the case of cognates with a high degree of semantic and conceptual congruence, the learner gets it right even during the interim lemma mediation stage, accounting for the rapidity with which cognates are acquired.

There are models that explain cognate facilitation through the architecture of the language-processing system and not through differences between the representations of cognates and non-cognates. In the bilingual interactive activation (BIA) model of lexical representation/processing (Dijkstra & van Heuven, 1998; Dijkstra, Grainger, & van Heuven, 1999), words similar to the input, either orthographically or phonologically, are activated in both languages, and nontarget items are inhibited by top-down processes. Costa et al. (2005) further suggest that the mechanism for prompting naming in the other language lies at the phonological (sublexical) level, with a cognate’s phonological content being activated via the target word as well as its counterpart.

It is possible that the presence of cognate pairs in the bilingual lexicon heightens a cognate's neighborhood density in the mental lexicon. Sherkina-Lieber's (2004) findings suggest that bilinguals (here Russian–English) perceive L2 items with cognates in their L1, but not those without L1 counterparts as having higher frequency than monolinguals do.

Using stimuli that included cognates and interlingual (L1–L2) homophones and homographs with different degrees of phonological and orthographic similarity respectively, Dijkstra, Grainger, and van Heuven (1999) investigated the connection between word recognition and orthographic neighborhood density among Dutch–English bilinguals. The results showed that semantic and orthographic overlap led to faster reaction times, but phonological overlap alone slowed the participants down. This explains why, in a number of recognition studies, cognates display a processing advantage, but interlingual (semantically unrelated) homophones do not.

Cognates: Pedagogical Issues

Hall (2002), based on research on cognate recognition among Spanish–English bilinguals, hypothesized that learners intuitively search through L1 lexical items for form–meaning matches with newly encountered L2 lexical items. However, there is also evidence that, despite their phonological/orthographic and semantic overlap, cognate pairs are often not recognized without explicit instruction, especially during the early stages of L2 acquisition and especially among young children. García (1991) found that fifth- and sixth-grade Spanish students learning English failed to recognize the relationships between everyday Spanish words and orthographically similar English cognate counterparts. In a similar setting, Nagy, García, Durgunoğlu, and Hancin-Bhatt (1993) found great variation in English learners' recognition of Spanish–English cognates in a reading comprehension task and concluded that recognizability increased with L2 lexical proficiency and age; while all the learners underused their knowledge of Spanish to grasp cognate words in English, the grade 4 students fared worse than students in grades 5 and 6. Similarly, Rukholm (2011) found that beginner learners of undergraduate Italian with a background in English or French did not make significantly higher gains than learners of languages genetically distant from Italian when acquiring cognates such as *cuore* 'heart' (cf. French *cœur*) or *ostacolo* (cf. English/French *obstacle*), presumably because they did not make any special connections between cognates. When recognition depends heavily on the written word, script differences can camouflage connections between cognates. This is witnessed in pairings of languages such as Hindi or Ukrainian with English where learners often fail to consider that the L1 and L2 may have cognate vocabulary (e.g., Hindi *विधवा* /vidʰva/ and *widow*; Ukrainian *церква* /'tserkva/ and *church* (Perhan, 2008)).

Bravo, Hiebert, & Pearson (2006) suggest that cognates be made a centerpiece of English instruction for Hispanic children in the USA since numerous ordinary Spanish words have English equivalents that belong to a higher "style" and are frequently used in academic/scientific writing (e.g., *enfermo*/*infirm*, *frío*/*frigid*). (This is generally true of vocabulary in all Romance languages.) The researchers' examination of a mini-corpus based on words found in primary school science curricula revealed a substantial number of cognates of this type (over 25%). Chen, Ramírez, Luo, Geva, and Ku (2011) compared Spanish- and Chinese-speaking Canadian fourth- and seventh-graders and found that the Spanish speakers out-performed the Chinese speakers on cognates in the Peabody Picture Vocabulary Test, whereas there was no such advantage for non-cognates. Moreover, for the Spanish speakers, length of residence in Canada only predicted knowledge of non-cognate vocabulary.

Trévaille (1996) found that instruction in recognizing and morphologically manipulating cognates helped beginner-level English-speaking university students of French to identify

cognates and infer their grammatical properties. (Note, however, that this treatment did not lead to higher reading comprehension scores on university reading tests.) Similarly, Perhan (2008) found that a group of Ukrainian-speaking undergraduates who had received explicit instruction on Ukrainian–English cognates and had completed a variety of tasks requiring elaborate processing (for example, pairs work to deduce the meanings of emboldened words in a text) out-performed not only those in a no-treatment group but also students who were simply exposed to these cognates in reading assignments that culminated in answering simple comprehension questions that did not hinge on understanding these cognates. Most importantly, the students who were given explicit instruction were able to generalize their knowledge of cognates to English items not previously encountered.

The inclusion of cognates in vocabulary tests is sometimes a contentious matter. Cobb (2000), for example, found that Francophone students enrolling in English courses in a Francophone university ended up with inflated scores on those segments of the Vocabulary Levels Test (VLT) (Nation, 1990) that contained a large proportion of French–English cognates. This was especially consequential since many of these learners were still struggling with extremely common Anglo-Saxon-derived words. However, Helms-Park, Dronjic, and Petrescu (2007) found that Romanian-speaking and Vietnamese-speaking students in a large Canadian university did equally well on the academic section of the VLT, despite the great preponderance of Latin-based cognates here. The authors surmised that, while the Romanian speakers might have known many cognates through minimal learning (or perhaps without even encountering them in an English-speaking environment), the Vietnamese-speaking students had learned these lexical items during their preparation for university study or through the frequent use of these items in everyday university contexts. Interestingly, in the 10,000-word general level (which featured less common words) the Romanian speakers clearly out-performed their Vietnamese counterparts on test items that were Romanian–English cognates. The authors recommend that cognates be included in a lexical test to whatever extent they exist in a frequency band or register targeted by the test. Nonetheless, when lexical tests are being validated, it seems to be a good idea to keep records of test takers’ language backgrounds in order to gauge to what extent some groups are advantaged as a result of cognate facilitation.

Cognitive Approaches to Communication Strategies

JEANNETTE LITTLEMORE

In second language acquisition research, the study of communication strategies (CSs) has traditionally gone hand in hand with interest in communicative competence, which is broadly defined as the ability not only to know the rules of the target language, but also to know how to use the language appropriately in different contexts. The most well-known model of communicative competence is Canale and Swain's (1980), which includes three main components: grammatical competence, sociolinguistic competence, and strategic competence. Canale and Swain's (1980) notion of strategic competence provided structure to the already flourishing field of CS research. CSs are defined by Tarone (1983, p. 62) as "the speaker's attempt to communicate meaningful content, in the face of some apparent lacks in the language system."

In trying to communicate, learners may have to make up for lack of knowledge of grammar or vocabulary. They might do so by relying on circumlocution, paraphrase, transfer from the L1 and so on. CSs differ from learning strategies in that they are used by learners, not to help them learn the target language, but to describe or approximate concepts and words they do not know or that cannot be instantaneously retrieved (Willems, 1987). However, some researchers, such as Bialystok (1983) maintain that this distinction between learning strategies and CSs is somewhat artificial. Bialystok argues that the use of so-called CSs can result in learning, and that many of the so-called learning strategies can also be used to communicate: "Any strategy may potentially operate as either a learning or a communication strategy: ideally the implementation of a strategy leaves a positive mark on both learning and communication" (Bialystok, 1983, p. 102). The *a priori* classification of strategies can, according to Bialystok, conceal important information about the types of strategies that L2 speakers select in order to communicate in any given situation.

There is some debate as to whether "communication strategies" or "compensation strategies" is a more appropriate term. Communication strategies comprise all strategies that are used to overcome obstacles to communication including, for example, accommodation and negotiating strategies. Compensation strategies, on the other hand, are specifically those strategies through which an L2 learner compensates for grammatical and vocabulary difficulties. Compensation strategies can therefore be viewed as a subset of CSs.

There have thus been different approaches to the study of CSs, and each carries its own definition. Researchers who take a sociolinguistic approach (e.g., Bachman & Palmer, 1996) tend to adopt a very broad definition which includes things such as planning one's message, negotiating meaning, or devising ways to interpret hidden ideas in texts. Researchers who take a more cognitive approach tend to focus mainly on "compensation" strategies, which learners use to compensate for gaps in their knowledge of the target language. The focus tends to be on spoken discourse. These researchers tend to argue that, as CSs are inherently mental procedures, research should focus on the cognitive processes underlying their use. They distinguish between planning and execution and make it an explicit categorization principle in their taxonomies.

2 COGNITIVE APPROACHES TO COMMUNICATION STRATEGIES

Much of the early research that was carried out into CSs was mainly descriptive. Researchers were interested in the types of CSs used by second language learners, usually with a view to establishing some way of classifying them. As with learning strategies, a number of overlapping and somewhat confusing hierarchical taxonomies emerged and researchers struggled to find a systematic way of classifying these strategies. The taxonomies were complicated, and at times self-contradictory. However, they are important in that they prepared the ground for later more empirical research in the area.

One of the first researchers to assemble CSs in an organized fashion was Tarone (1978, 1980). She based her taxonomy on a data set of nine subjects. The subjects were asked to describe, in both their native language and the target language, a complex illustration containing seven objects for which they probably would not know the word in the target language. There were thus only seven target language concepts. Although the data set was small, it was sufficient to enable Tarone to uncover most of the CSs that are discussed in later studies and at the same time demonstrate the consistency with which learners adopt these strategies in communicative situations of this type.

The CSs in Tarone's taxonomy were divided into five major categories, three of which were further subdivided:

1. *Avoidance*
 - a. *Topic avoidance*—the student omitted salient but lexically difficult objects.
 - b. *Message abandonment*—the student started to tackle the difficulty but then gave up.
2. *Paraphrase*—"rewording of the message in an alternate, acceptable target language construction, in situations where the appropriate form or construction is not known or not yet stable" (Tarone, 1978, p. 198)
 - a. *Approximation*—"the use of a single target language vocabulary item or structure, which the learner knows is not correct, but which shares enough semantic features in common with the desired item to satisfy the learner" (1978, p. 198). Example: "worm" (silkworm).
 - b. *Word coinage*—"the learner makes up a new word in order to communicate a desired concept" (1978, p. 198). Example: "airball" (balloon).
 - c. *Circumlocution*—"a worldly (sic) extended process in which the learner describes the characteristics or elements of the object or action instead of using the appropriate target language structure" (1978, p. 198). Example: "she is smoking something. I don't know what's its name. That's uh Persian, and we use in Turkey a lot of" (water pipe).
3. *Conscious transfer*
 - a. *Literal translation*—this is said to occur when the subject takes an L1 or L3 expression and translates it directly into the L2.
 - b. *Language switch*—this is the straightforward insertion of words from another language.
4. *Appeal for assistance*—this is said to occur when the learner consults any source of authority.
5. *Mime*—this strategy includes all nonverbal accompaniments to communication, particularly those that serve in the place of a missing target language word.

One problem with the early CS research was what Bialystok (1990) describes as the "modularity fallacy" which, she alleges, dominated the early communication strategy research. This fallacy, according to Bialystok, led researchers to believe that the CSs were separate and independent from one another. It led to an overreliance on surface forms, and caused a proliferation of categories of CSs which lacked psychological validity and reliability. Bialystok (1990, p. 80) also points out that "attempts to document both the reliability and the validity of the taxonomic classifications have led to disappointing results."

Several researchers have attempted to go beyond the “taxonomy” approach to the study of CSs. Faerch and Kasper (e.g., 1984) first moved away from surface phenomena to examine underlying processes, and discussed strategies in terms of two main behaviors, namely reduction (e.g., avoidance of errors) and achievement (compensatory strategies, e.g., transfer). Kumaravadivelu (1988) identified three psychological processes that he maintains underlie all CSs. These are *overgeneralization*, *creative transfer* and *cultural relativity*. Overgeneralization occurs when “learners make inductive generalization about the target language system on the basis of the data to which they are exposed” (1990, p. 316). In creative transfer, learners attribute to a lexical item “all the functions . . . of its assumed first language translation equivalent” (1990, p. 316). In cultural relativity, learners employ thought patterns that are characteristic of their culture, which leads them to produce utterances that differ from the rhetorical norms of the target language.

Poulisse (1990, 1993) (sometimes referred to as “The Nijmegen Project”), also aimed to go beyond linguistic differences and examine the underlying processes. Instead of creating a product-oriented taxonomy, this research aimed to produce a context-free, process-based taxonomy of CSs that met three basic requirements: (a) parsimony—the fewer strategies the better; (b) generalizability—independence of variation across speakers, tasks, languages, and proficiency levels; and (c) psychological plausibility (most important)—a taxonomy should be “informed by what is currently known about language processing, cognition and problem-solving behavior” (Dornyei & Scott, 1997, p. 199). Basing their work on Levelt’s (1989) model of speech processing, they propose a process-based analysis consisting of two “strategy families”: the conceptual strategy family and the linguistic strategy family. If learners compensate for a missing word by exploiting conceptual knowledge they are thought to be using a conceptual strategy, whereas if they attempt to compensate through linguistic knowledge they are thought to be using a linguistic strategy. Poulisse (1993) extended the taxonomy of CSs to include three “strategy families”: “substitution;” “substitution plus;” and “reconceptualization.” Substitution strategies are used when the speaker replaces the intended lexical item with another one, either from the L1 or from the L2 (for example, the use of the L2 word “animal” for “rabbit,” or the L1 word “house” for the L2 word “maison”). Substitution plus strategies involve the use of a substitution strategy, but with an added morphological or phonological development (for example, the creation of the verb “ironize” on the basis of the noun “iron”). Reconceptualization strategies involve “a change in the preverbal message involving more than a single chunk” (p. 181) (for example, “it’s green and you eat it with potatoes” for “spinach”). These involve componential analysis (it’s got a head, a body, and four legs) and/or the provision of information about what the item does, what it’s for, where it can be found, and so on.

Other researchers who have taken a cognitive approach to CSs include Chen (1990), who divided CSs into “linguistic” and “knowledge-based” strategies; Marrie and Netten (1991), who divided CSs into “achievement” and “reduction” strategies; and Bialystok (1990), who divides strategies into those that involve “analysis” (i.e., exploring one’s intended meaning) and those that involve “control” (i.e., directing one’s attention to a particular aspect of the communication problem). Khanji (1996) made an initial attempt to combine both the interactional and psycholinguistic approaches to the study of CSs and has developed a taxonomy which, he claims, incorporates both views. In his taxonomy he contrasts self-regulating strategies with topic-regulating strategies, showing yet another way of taking a cognitive approach to CS research.

More recent developments in the field have included a focus on the use of gesture as a compensation strategy. For example, Gullberg (1998) found gestural CSs to be particularly useful as they involved both interlocutors in the joint solution of the task and help to create redundancy. Olsher (2008), who looked at repair turns in student interactions, found that gesture played an important role in explaining or enhancing the meaning of the

repeated segments, and that it contributed to the interactional understanding of the repaired turn. Finally, Mori and Hayashi (2006) showed how gesture is used to build intersubjectivity and common frames of reference in dialogues between native speakers and second language learners. Once these common frames of reference have been built up, the native speaker has an idea of what the language learner wants to say and can help provide the missing vocabulary to the learner. All of these studies illustrate how this newly found focus on gesture can help to build bridges between purely “cognitive” approaches to CSs and approaches that have taken a more interactional perspective. They also promise to provide new ways of exploring the relationship between CS usage, language learning and the employment of more generic, less “language-specific” cognitive processes.

Cognitive Approaches to Translation

HANNA RISKU

Obviously, there is more to translation than just associating words in one language with those in another. Cognitive scientific approaches to translation try to understand and explain the workings of translators' minds: How do translators and the other actors involved in translation create meaning in the situations and texts they handle? How do they arrive at their strategies and choices? How does their cultural and linguistic background influence their thinking and understanding? How do they develop translation competence?

All cognitive scientific approaches to answering these questions have one thing in common: they do not restrict their description to intelligent behavior like learning, problem solving, and translation. Their main goal is to explain the development and workings of the mental processes that make complex cognitive behavior like translation possible (Shlesinger, 2000; Thagard, 2005, p. 3). This is why (and how) cognitive approaches differ from other—e.g., linguistic or psychological—approaches to translation: They refer to and expand existing cognitive scientific models of the mind to describe the processes which might serve to explain the behavior and choices of translators.

Cognitive translation research is closely related to the ever-increasing process research in translation studies, which uses different methods to observe the actual chronological activity of translating by different groups of participants with different text types and different contexts. What makes cognitive translation research cognitive is the fact that it tries to look "behind" the observable processes and, when doing so, refers to certain cognitive scientific concepts or approaches as a framework (which can thus be confirmed or disproved). Consequently, cognitive approaches focus clearly on the people and processes involved in translation and employ a primarily descriptive—as opposed to a normative—mode of research, applying various empirical and experimental research designs. Thus, they can be seen as part of "translator studies," the recent tendency in translation studies to focus explicitly on the translator, rather than on translations as texts (Chesterman, 2009, p. 13: "A broad outline of Translator Studies would cover sociology, culture and cognition, all looking at the translator's agency, in different ways").

Instead of only analyzing texts or external behavior (in a behaviorist manner), cognitive scientists consider inner processes. The mind is no longer a "black box." There are, for example, now sophisticated methods and instruments available which make the neurological processes in the brain visible. However, the cognitive processes as such are neither visible nor self-evident, and there are several competing hypotheses in cognitive science regarding the meaning of the neurological and behavioral evidence. One question that remains open is, for example, the location of meaning. Does meaning reside in words, languages, texts (Wilss, 1988, p. 104), neuronal patterns, brains, or interaction? Consequently, the different cognitive scientific approaches propose different answers to the question of what happens in the minds of translators.

An understanding of cognition is a prerequisite for explaining many of the practical tasks relevant in translation, since these tasks are based on thinking, learning, and understanding. What are the effects of different methods of teaching and learning? Why do translators find some things easy to translate, yet others difficult? How can meaning be

assigned to target situations and source texts? Are there any universal elements to thought processes which remain the same across different cultures and serve as a basis for translation? Can machine translation programs actually show us how “human translators” work—or can they only show us how people *don’t* work? Applied research can address, for example, the following questions: What can be done in the production process to make texts understandable? What kinds of tools support translators in their problem-solving processes? How should translators organize their work?

Methodological Approaches

Modern cognitive scientists and cognitive science methods often have their roots in psychology, artificial intelligence, philosophy, linguistics, anthropology, and neuroscience. For example, psycholinguistic research on bilingualism has had a major effect on translation studies (and an even stronger effect on interpreting studies; Campbell & Wakim, 2007), while text comprehension and production research has provided important discourse processing concepts (van Dijk & Kintsch, 1983). All these disciplines bring their own methodological traditions and competences to the study of cognition. In translation studies, the methods used to date have included, for example, introspection (Seleskovitch & Lederer, 1984—later criticized for its insufficient empirical basis and for relying on the authors’ own experience, see e.g., Pöschhacker, 2000, pp. 67–8—and Seleskovitch, 1988), neurological EEG measurements of brain activity (Kurz, 1996), theoretical analysis (Wilss, 1988; Risku, 1998), think-aloud protocols (TAPs) of individual language learners and translators (Krings, 1986; Lörcher, 1991; Jääskeläinen & Tirkkonen-Condit, 1991; Tirkkonen-Condit & Jääskeläinen, 2000) and groups of translators (Kußmaul, 2000), participant observation (Risku, 2009), tracking/logging the translation process on computer screens (Jakobsen, 1999), and eye-tracking (see e.g., Göpferich, Jakobsen, & Mees, 2008; several contributions in Shreve & Angelone, 2010a; Dragsted, 2010; Shreve, Lacruz, & Angelone, 2010; Rydning & Lachaud, 2010; Alves, Pagano, Neumann, Steiner, & Hansen-Schirra, 2010; O’Brien, 2010). With methodological innovation having become a major topic in cognitive translology (Shreve & Angelone, 2010b, pp. 6–7), increasing attention is also placed on combining translation process observation with translation product analysis and corpus-based translation studies (Rydning & Lachaud, 2010; Alves et al., 2010; Halverson, 2010; see also Malmkjær, 2000, p. 164).

Over time, the research design used in cognitive studies of translation has moved away from the study of nontranslators or learners in conditions that bear little relevance to professional translation practice toward the description of real-life(-like) translation by professionals. Important first moves in this direction were the change of test persons from beginners to semiprofessionals by Krings (1988) and the comparisons of beginners with professionals by Jääskeläinen and Tirkkonen-Condit (1991; for a summary of the empirical evidence of the differences between the way beginners and professionals work, see Fraser, 2000, pp. 111–12 and Kußmaul, 2009, p. 317). For example, professionals have been observed to use global, recursive strategies instead of local, linear strategies and to write longer segments of text at a time, leading to the hypothesis that they process larger, meaning-based units (Kußmaul, 2009, p. 317). The growing practical relevance of the translation processes studied increased the potential for applied research, since it enabled researchers, for example, to use the results to develop suitable didactic measures to support the learning and teaching of translation competences (Kußmaul, 1995; Kiraly, 2000; Hansen, 2006).

At the same time, defining professionalism and expertise in an operationalizable manner has become one of the current themes in cognitive translation studies. In light of the (inferior) quality of translations produced by some professionals in empirical studies, the

pragmatic solely education and/or length of work experience definition has proved insufficient when looking to identify “best practice” and best performance (Jääskeläinen, 2010). The issues of acquiring the social role of a professional translator (Holz-Mänttari, 1984; Sela-Sheffy, 2005) and acquiring the expertise to perform excellently in a field can thus be seen as distinct yet closely related research topics (for classic typologies of developing expertise, see Dreyfus & Dreyfus, 1986 and Bereiter & Scardamalia, 1987, 1993). After all, as situated and constructivist approaches to cognition show (see below), the social and cognitive perspectives are intertwined: the possibility of assuming the role of a professional in a production network facilitates and enables the acquisition and implementation of the expertise needed for the task (Kiraly, 2000; Risku, 1998, 2009).

Technology has often provided a framework for new scientific models. For example, the development of the models used in the cognitive approaches to translation has been oriented on the computer metaphor (translation as information processing and symbol manipulation) since the 1960s, on the neuronal network metaphor (connectionist models of translation) since the 1980s, and on the social networks metaphor (social constructivist and situated translation) since the 1990s. The summary of the development of the cognitive approaches to translation provided below uses these as a framework:

- information processing (translation as code switching and symbol manipulation),
- neural networks and connectionism (translation as an experiential, cultural act), and
- situated cognition (translation as socioculturally situated interaction).

Translation as Information Processing and Symbol Manipulation

In the early days of translation (and communication) studies, the telephone or coding and recoding in different linguistic systems served as an explanatory model (Jakobson, 1959; Kade, 1968; Koller, 1978). According to this classic model, translators work like code switchers: they replace the elements and rules in one coding system with the elements and rules of another (Wilss, 1992, p. 110). Once a person has learned a language system and its corresponding elements and rules in another language system, they can basically rely on their own dexterity and proficiency—a bit like a machine (e.g., a gramophone, see Wilss, 1992, p. 109). By this principle, the function of a text could be determined by means of system-linguistic analysis. However, this model proved to be too simplistic: sense and meaning cannot be primarily or exclusively explained through reaction to stimuli or by decoding symbols.

If the brain works like a computer rather than a telephone—an assumption that takes us into the domain of modern cognitive science—translation is still a matter of codes, rules, and uncovering the binding function of the text, but in a far more subtle sense. The first and probably best known—although now much disputed—information processing as symbol manipulation approach combines the notion of an inherent universal system of rules (Chomsky’s transformational-generative grammar, 1965) with the notion of thinking as a logical operation on symbols (Simon, 1970; Fodor, 1983). According to this principle, people of all cultures think with the help of the same language structure (language of thought), which we use when translating. Different languages are merely surface phenomena which can be associated back to the basic rules, and thus to their meaning, using syntactic analysis. If all perception and understanding is a coding in internal symbols, and all thinking is an operation of these symbols, translation is also a kind of—albeit complicated—computer program.

Equivalence theory approaches to translation imply a corresponding picture of translation as the comparison of linguistic and cultural systems. For example, semantic networks

provide a method of systematically structuring and comparing meaning by means of symbol and concept systems based on shared properties. According to these approaches, the relevant properties, concept networks, and linguistic conventions used in different cultures lay the basis for translation as information processing and linguistic transfer.

Translation as an Experiential, Cultural Act

The previously dominant notion of information processing as a rule-based manipulation of symbols has proved to be highly problematic in recent years. Even the smallest change in the task or system causes the model to break down—while humans are able to master and understand even incomplete and grammatically incorrect information with apparent ease. Traditional algorithms might out-perform the logical and mathematical calculation abilities of the human brain, but they fail miserably with the day-to-day routine tasks encountered in the “natural” world—even ants are far superior in this context than any “autonomous machine.” This was one of the reasons why it was assumed that humans do not think and understand in terms of semantic characteristics, but in terms of experiential, emotionally loaded typical examples—or prototypes (Rosch, 1973). The prototype theory was used in translation studies, for example, by Snell-Hornby (1988, p. 27), Hönig (1997), and Kußmaul (2000). Drawing on Lakoff (1982, p. 16), Snell-Hornby emphasizes the fuzzy, culturally constructed nature of our cognitive categorizations and their “blurred edges,” which are influenced by the body, by cultural myths, and by stereotypes. Depending on our culture and situation, we categorize differently and judge certain objects to be more representative than others. The meaning of the word *bird* is not defined across all cultures based on its characteristics as a two-legged, two-winged, beaked vertebrate that can fly. Instead, humans associate it with the species they are most familiar with or which is most prevalent in their society, thus instantaneously associating it with an individual and, at the same time, culturally dependent world of colors, sounds, and movement. Consequently, our understanding of a text necessarily depends on our nonlinguistic presuppositions and preconceptions.

The prototype theory well and truly rocks the ideal of translation as a subject-independent recoding of a linguistically transparent meaning. It is one of a group of cognitive models which postulate different experience-based (in contrast to symbol- and property-oriented) units of thought. These units are referred to, for example, as frames, scripts, schemas, scenes, or scenarios. In translation studies, Vannerem and Snell-Hornby (1986) implemented Fillmore’s (1977) model of scenes and frames to explain the experiential basis of text analysis and production in translation. All of these approaches are based on the assumption that the world knowledge gained through individual experience plays a dominant role in thinking, understanding, and learning. The term “schema” itself can be traced back to Kant, Bartlett, and Piaget and is now used in the cognitive sciences to describe the rough patterns of action and thought which we reconstruct accordingly when we encounter a situation and which are modified over the course of time. Thus, all understanding is initially based on a contextual interpretation of our own patterns of thought. We don’t begin to understand and produce texts when we read the first words they contain, we begin to do so when we activate our understanding of the particular situation, which leads us to expect certain types of texts and content. Translators can therefore never *reproduce*, they offer possibilities for new constructions of meaning.

The scheme theory model served to explain the emotional, flexible, contextual, creative, and constructive sides to translation. Translators, it would seem, do not simply process symbolic information based on a set of rules, they construct meaning in concrete situations. In doing so, they draw on their own experiential meaning, i.e., they are self-referential.

Understanding was thus explained as an interaction between situation-specific inputs and internal, individual, and culture-specific models. Scientists in the field of artificial intelligence were able to simulate this process in the 1980s. Cognition was modeled as pattern recognition using artificial neural networks. In the cognitive sciences, this created the paradigm of connectionism or parallel distributed processing (Rumelhart & McClelland, 1986). This approach not only attempts to provide a functional explanation for human cognition, it also draws on the structure of the brain with its millions upon millions of connected nerve cells. According to this approach, there are no preprogrammed symbols and rules. We don't store knowledge somewhere as individual pieces of data, we develop and activate patterns with connections of different strength between closely linked neurons. Knowledge is not located in the individual neurons, it is distributed across the entire network—hence the term “parallel distributed processing.” The use of abstract (computer) models of biological neural networks is referred to as connectionism, a term now also applied to the whole approach. So computers also play an important role here, albeit only as tools. There is no suggestion of a universal calculation algorithm; the network itself learns—through individual experience and by using the available connections—to recognize regularities in its environment. The meaning of symbols is actively learned in concrete interactions on the sub-symbolic level. The repetition of situations creates relative (individual and cultural) stability, but meaning is nonetheless in a constant process of change.

The connectionist networks approach provides explanations for many translation phenomena that were left unanswered by the symbol manipulation approach. Translators (like connectionist networks) can also activate copious patterns and use different interpretations to suit the situative, textual, and internal context, even when the source text is unclear. Their culture-specific knowledge and experience and their prior knowledge of the target group affect the way they translate. Thus, connectionists tackle the wider epistemological and hermeneutic problem of “framing” (Gadamer, 1972; Wheeler, 2008): They try to explain our ability to take account of a situation, base our interpretations on what is relevant in a specific situation, and limit the scope of information that is (re)considered in the process. In translation studies, Gutt (1991) discusses the problem of endless circles of inferences in terms of relevance, based on Sperber and Wilson's (1986) relevance theory. Hönig (1997, p. 50) combines experience-based—and thus culture-specific—world knowledge and its manifestation in translation into a connectionist model of constructive translation. In doing so, these experts formulated cognitive approaches to translation which explain why translators cannot simply reproduce “the” functions and meanings of a text in another culture and situation, but have to take a responsible role as decision makers, experts, and interpreters (Nord, 1997).

The move to a view of cognition as a sub-symbolic and linguistically nontransparent activity relativizes the adequacy of “thinking aloud” as a data-gathering method: Since every verbalization is already an interpretation, and possibly even a rationalization of the internal, intro- and retrospectively inaccessible process, the validity of TAPs has been criticized in translation studies (e.g., Bernardini, 2001; Jakobsen, 2003). TAPs were the preferred method of data collection in early process studies and resulted in a wealth of hypotheses on the underlying cognitive processes; nowadays, they are increasingly combined with other methods, and triangulation is preferred in order to avoid overemphasizing the translators' verbalized accounts of their own action (Alves, 2003).

Translation as Socioculturally Situated Interaction

In the 1980s, the cognitive sciences experienced growing criticism of the symbol systems and information-processing hypothesis. This period also marked the birth of connectionism.

In the 1990s, there was growing dissatisfaction with the connectionist models because of the low priority they accorded to the social and artifact-mediated aspects of intelligence. Parallel developments in different disciplines—from developmental psychology (Thelen & Smith, 1994) to learning theories (Lave & Wenger, 1991), robotics (Brooks, 1995), dynamic systems theory (van Gelder, 1998), and human–computer interaction (Suchman, 1987)—acknowledged the importance of social and physical interaction in cognition. Consequently, scholars combined their efforts to tackle the sociocultural situatedness of cognition (Frank, Dirven, Ziemke, & Bernárdez, 2008), marking the birth of a new approach: situated, embodied cognition. Rather than explaining cognition as the recognition, reconstruction, and use of relatively stable schemas and patterns in the brain (with scientific roots in Piaget’s [1954] developmental psychology), situated, embodied cognition views cognition as agent–environment interaction in a psycho-social, ecological system (with roots in Vygotsky’s [1962] theory of language and thinking). Here, cognition is seen as situated action in complex physical and social situations—not as the recycling and reuse of prior knowledge. People cannot “borrow” meaning from their inherent cognitive abilities, or from their environment, or from other people. Meaning cannot be localized on paper or in the brain, it results from our interaction with our current environment. Thus, the object of study is extended from the brain to its interaction with body and the environment, emphasizing the importance of social interaction and interaction with cultural artifacts.

The situated cognition approach was brought to translation studies for example by Kiraly (2000) and Risku (2009; see also Prunč, 2007, p. 197; Muñoz Martín, 2010) and to the neighboring discipline of terminology for example by Temmerman (2008). Whereas Kiraly presents a social constructivist approach to translator education, Risku (2009) uses field studies with participant observation to illustrate the role of the social and physical environment, especially the influence of the tools of the trade (translation technology) and social roles in interaction. According to the situated cognition approach, one of the main reasons for our intelligence is that we delegate knowledge to our environment and motions. We use tools and instruments. Thus, much of the complexity is “scaffolded” by external structures (Clark, 1997, pp. 45–6), and we reduce the need to store, search for, and process knowledge in the brain.

The principle of cognitive economy manifests itself in many different ways. We design translation offices and technologies to suit their specific purpose; we use specific forms of discourse in various conversations; we create checklists to coordinate actions and reduce the cognitive load on our memory. Rooms, organizations, forms of discourse, and actions which serve other actions become tools in the wider sense of the word (Hendriks-Jansen, 1996). They put a framework, a cultural scaffolding, around our actions and understanding. External aids such as terminologies, grammars, text analysis heuristics, and scientific models are all used as scaffolds: they form teaching, learning, and organizational aids.

Process research in translation has concentrated to a large extent on describing translation as a problem-solving and decision-making process. The focus has been placed in particular on those phases in which the translator faces difficulties, the translation process becomes slow and the translator tries to find a solution for a problematic text segment. By doing so, it has implicitly adopted an information-processing view on translation, looking at it as a mental operation on internal processing units and defining a multitude of different mental “process operators,” such as macro and micro strategies, techniques, methods, and procedures (Gil Bardaji, 2009). However, as Muñoz Martín (2010) points out, if we take the consequences of situated, embedded cognition seriously (Risku, 2010), unproblematic text segments and “unconscious” processes are just as interesting as problematic segments: they provide information on the ability to interact fluently with the material in hand and thus might prove very relevant for the description of translation expertise.

The “extensions to cognitive science” brought by the situated, embodied cognition approach include “bodies, the world, and dynamic systems” on the one hand, and “societies” on the other (Thagard, 2005). The role of the social factors in cognition has also been taken into account in the recent developments of translation studies. With reference to Vygotsky’s (1962) concept of the “zone of proximal development,” Kiraly (2000, p. 40) notes that essential internal developmental processes are only able to operate when learners interact with people in their environment and with their peers. He develops a view of situated learning by learning through authentic actions in translation education. As didactic methods, sociocognitive apprenticeship (Brown, Collins, & Duguid, 1989, p. 39) and legitimate peripheral participation (Lave & Wenger, 1991) take into account that learning to translate is based on assuming roles and the corresponding behavior associated with these roles in social situations. Cognitive and social skills are closely interrelated. By assuming the role of the expert, we develop the ability to cope with the challenges this role imposes (Lave & Wenger, 1991). Thus, professional identity and competence are not only associated with the individual, but also with social processes or other processes with a strong social element.

The situated cognition approach to translation emphasizes the social organization of translation by practitioners (Risku, 2009). Close attention is given to the communities of practice (Risku & Dickinson, 2009), the actor networks (Buzelin, 2005), and the computer-supported cooperative work in which complex activities are negotiated (see Wagner, 1997). The social elements in translation studies (Wolf, 2006) are thus visible in the cognitive approaches to translation, as they increasingly expand their scope of attention from the individual translator to the study of networks and collaboration in translation (Kiraly, 2000).

Cognitive Constructivism

GEORGE G. HRUBY AND ANTHONY B. ROEGIER

Cognitive constructivism is an umbrella term for a host of related epistemological and psychological theories about the nature of knowledge and how it is formed through a knower's mental (hence *cognitive*) processes. As the metaphor of *construction* implies, cognitive constructivist theories assume that knowledge is a thing made by the mind rather than received from a source. Knowledge, in this view, is not transmitted all of a piece with meaning intact or contained, nor accrued piecemeal and then reconstituted. Rather, knowledge is said to be *constructed*, or actively structured, by a knower's mental processes even as particular purposes and contextual constraints guide the result. The anthropomorphic image of a builder or *bricoleur* (tinkerer) creating a knowledge structure, edifice, or machine is occasionally employed to illustrate this metaphor of mental process, and may be helpful if not taken too literally.

In conjunction with the idea that knowledge or understanding is constructed, cognitive constructivists hold that the structure of knowledge (as in a specific network of associations) is crucial to its functionality. As one result, pre-existing knowledge structures impose a degree of guidance, affordance, or constraint on the development of new knowledge. In more pedestrian terms, we make sense of our memories and perceptions, including *new* experiences and information, by the light of what we already know. We recognize and comprehend the familiar by reference to what we already know, of course, but we also make sense of novel experiences by comparison and analogy with what we already know. To define an unknown word, for instance, we use already known words. In short, bringing perceptions into accord with the structure of what we already know, and thereby expanding the structure of what we know, is the central task of knowledge construction.

Granted, all but the most extremely simplistic, reductionist, or empiricist theories of knowledge would accede at least some role for prior experience as a crucial component in knowledge formation (cf. Locke, 1689/1996; Vico, 1699/1993). But cognitive constructivism takes this assumption further under the theoretical emphases of *structuralism*, particularly the claim that meaning is to be found not inherent in the essentially arbitrary elements of a system, but as a result of their regularly ordered interrelationships (as developed by Saussure, 1910/1983). Thus, to make sense of our perceptions, these must be ordered, structured, or constructed into an arrangement in accordance with the semiotic grammar of a representational system. For *cognitive* constructivism, this system is the mind, which is presumed to be made up of an ordered arrangement of informational representations as well as cognitive processes for performing operations on those representations. It is the necessary ordering of said representations that is the basis for claiming that knowledge (memory, understanding, experience) is, and indeed must be, *constructed*.

Several implications follow from these basic tenets of cognitive constructivist theory: (a) knowledge is neither fixed nor absolute; (b) it is variably reconstructed with each recollection or use; (c) these customized reconstructions vary to suit the knower's immediate needs regarding a particular goal, task, or situation (which provides still more experience for adjustment of the underlying knowledge base); and (d) different individuals, with different prior knowledge, perspectives, histories, and values, will generate slightly different recollections of the "same" event. As a result, (e) different observers take away somewhat

different new knowledge from the “same” learning experience. Most generally accepted would be that (f) the role of prior knowledge in the acquisition of new knowledge requires that effective educational regimens be graduated in design.

A concrete example of knowledge variance (as suggested in items b and c of the previous paragraph) would be the rereading of a favorite book by a single individual. The experience of the second reading is notably different from that of the first reading even though the reader and the printed words on the page are the same in both cases. The difference is due to the reader’s intervening experience (including having experienced and thought about the first reading of the book). This experience changes the content and structure of the reader’s prior knowledge, resulting in different prior knowledge brought to bear in the second reading, thus altering what the reader recognizes, associates, anticipates, and values.

Descriptions of how this works can be seen to fall along a continuum of theories. These range from suggesting that the construction of knowledge is a deliberately willful and strategic act on the part of a knower attempting to make sense of perceptions or insights on behalf of some objective, to suggesting that the construction of knowledge is an automatic biological process involving the adaptive development of neural structures in response to activation, which then channel the future behavior and potential experiences of an organism as it grows in transactive response with its environment (these two views are not mutually exclusive, however, as they describe different scales of organization).

Most theories of cognitive constructivism, however, fall between the consciously strategic and biologically automatic views, with most emphasizing representational mental processes, largely nonconscious but consciously mediatable, that account for the resulting structure and accessibility of a knower’s knowledge. Philosophically, the roots of cognitive constructivism can be found in Western rationalist epistemology with its emphasis on logical coherence over sensory correspondence as a gateway to truth (e.g., Descartes, 1596–1650), as well as in empiricist models of knowledge built of networks of associations gleaned from experience (e.g., Hume, 1711–76). These idioms were incorporated into theories about the role of experience in conceptual growth in functional psychology (e.g., James, 1842–1910; Dewey, 1859–1952). These foundations were further amended by psychological research resulting in the articulation of what is currently taken to be cognitive constructivism.

Cognitive constructivist thinkers have cited the work of German philosopher Immanuel Kant (1724–1804) as a foundation (e.g., Kant, 1781/2008), particularly his notion of archetypal categories for thought and their use in ordering our sensations of the world. Kant’s systematically rigorous idealist philosophy laid the groundwork for structuralism more generally, and particularly its subsequent use as a psychological idiom in the 20th century. Credit for moving these ideas into psychology is principally given to the Swiss developmental psychologist Jean Piaget (1896–1980). Piaget actually referred to himself as a *genetic epistemologist*, however, which underscores both the philosophical and biological roots of his enterprise (*genetic* in this sense simply means growth-related, not genomic; thus, Piaget saw himself as a researcher of knowledge growth, assuming it was an essentially organic process).

Piaget, relying on case-based observation, concluded that human thought develops through interrelation with the environment but in dependably sequenced, biologically necessary stages toward adaptively structured knowledge and skills. These cognitive stages emerge in tandem with other developing attributes of behavior and emotion in a necessarily complex, organic fashion toward adaptive functionality. The four basic stages of cognitive development he proposed were (a) the development of sensory-motor schemas in infancy, (b) the development of pre-operational schemas (representations) in early childhood, (c) the development of concrete schemas (logical operations) in mid-childhood, and (d) the development of formal schemas (operations on hypotheticals) in late childhood/prepubescence.

Piaget (1937/1957) suggested these developmental stages are realized through the learning of specific *schemas* (regimens, skill sets, protocols), which initially relate to immediate developmental needs, but can be applied by analogy to later novel experiences, situations,

or scenarios. Major structural renovations to the knowledge base of the sort that mark a behavioral stage-shift are necessary when schemas which were previously adaptive come to prove inadequate for a child's needs. The cognitive disequilibrium created by this inadequacy prompts the child's exploratory behaviors toward a more satisfying relationship with the environment, fostering the next stage in the developmental sequence.

For instance, an infant at birth has a propensity for suckling and gentle grasping and will apply these behaviors to any object it can take to hand. As a result, the infant develops coordinated tactile and motor skills (sensory-motor stage), and patterns of multimodal association necessary for the development of object identification and, subsequently, linguistic representation (preoperational stage).

Piaget presumed a changing (but at any given time definitively structured) knowledge base that requires adaptation for growth. The adaptive mental processes of *assimilation* (adjusting new knowledge to match prior knowledge) and *accommodation* (adjusting prior knowledge to match new knowledge) allow for the growth and modification of a knower's knowledge base. As Piaget phrased it, intelligence organizes the world by organizing itself.

Piaget's ideas have faced both theoretical and empirical challenges over the decades, and were much modified over his long career; but his importance in articulating the construct of mental learning processes, cognitive development, and the structured nature of knowledge (albeit within an organic idiom) remains unassailable. Piaget's insights were very much of a time when post-Hegelian and Darwinian themes were common intellectual parlance. Other thinkers articulated similar ideas. For instance, Piaget's use of equilibration and adaptation as dynamical processes for cognitive development were presaged by the American functional psychologist John Dewey (e.g., 1896).

Another early contributor to the psychology of knowledge construction was F. C. Bartlett (1886–1969), who elaborated constructivist principles to account for the problem of knowledge variation and memory. His experiments demonstrated that memories are not exactly duplicated; rather, their details tend to alter from recollection to recollection (or across social sharings). This suggested to Bartlett that memories were not the mere repeating of traces (as had been suggested by the psychologist Hermann Ebbinghaus, 1850–1909), but were adaptive reconstructions of underlying *memory schemas*, a complex of associated representations (unrelated to Piaget's notion of behavioral schemas; inspired more by the ideas of neurophysiologist Henry Head, 1861–1940). Bartlett (1932/1995) noted that reconstructions of schemas vary not at random, but in general accord with the purpose or context of the recollection. Not surprisingly, therefore, Bartlett is also noted for his attention to the role of contexts and social conditions for learning and memory, an emphasis underappreciated in the British academy of his time.

In spite of the noteworthy theoretical and empirical advances of Dewey, Piaget, Bartlett, and others, it was not until the development of cognitive psychology, beginning in the 1950s (e.g., Neisser, 1967), that cognitive constructivism could be operationalized and researched. This was made possible by cognitive psychology's use of the computer program as a mechanistic metaphor for mental structure and process. At the time, computer programs were relatively simple and linear, and their logic was easy to map in two-dimensional flowcharts, making them suitable as a metaphor for cognitive modeling. The power of this metaphor lies in the fact that computer programs require logical precision in their structure to carry out their function. A computer program that lacks such precision does not function. From this it was deduced that the structure of a functioning mind must allow for the kind of exactitude made possible by computer program logic. (A desire for such exactness in language-based representational systems had already been the failed dream of the Logical Positivists of the early 20th century, who conceded their project at about the time that this new turn in psychology began.)

Insights from experimental psychology (Miller, 1956), psycholinguistics (Chomsky, 1957), and the then budding field of artificial intelligence (Newell & Simon, 1956) were conjoined

4 COGNITIVE CONSTRUCTIVISM

within this metaphor of the-mind-as-software-program. As such, the mind's program structure could be indirectly researched through back propagation from functional (or failed) results in closely controlled experiments. This so-called *cognitive revolution* transformed vague ideas about developmental epistemology into an empirically grounded agenda for cognitive psychology. A surge of governmental funding for research in the basic and applied social sciences at the time supported a boom in university-based cognitive research laboratories and graduate programs, adding momentum to research on mental structure.

A curious characteristic of this new approach to studying the mind was that it took the deliberate construction of knowledge to heart not just as an ontological assertion, but as an epistemological precept and methodological foundation as well. Cognitive researchers dismissed positivistic behavioral measurement that lacked acknowledgment of the theory or knowledge presumed in the investigation, as behaviorists had done (e.g., Skinner, 1953; cf. Chomsky, 1959). Rather, cognitive psychologists insisted that a true science of the mind and behavior required carefully formulated theories and models of causation from which testable hypotheses could be drawn for potential falsification (Popper, 1935/1959). Thus, the deep structure of knowledge and cognitive process was at once an assumption, target, and means of psychological investigation, a situation that critics rightly claimed warranted concern over circular reasoning in research design. But the explicit call for rationalist science over mere empirical measurement (Chomsky, 1959) set cognitive psychology apart from the positivism of earlier experimental studies of behavior.

Although research on mental structure initially promised a more certain model of knowledge construction, the emphasis on theoretical modeling generated instead an ever-greater plurality of models and divergence of theory. But three obvious strands in this diversity can be traced. One strand, emboldened by advances in information technology, demonstrated a greater interest in the structural necessity of internal coherence and operative feasibility, and hypothesized hierarchically embedded program structures (as in those resulting from propositional analysis, e.g., Kintsch, 1998). This thread came to inform educational work on automatized processes, skills acquisition, and disabilities interventions.

The second strand, emanating out of developmental psychology, took a greater interest in the purposively directive influence of the developing organism or learner, functionally or consciously mediating the direction of its knowledge construction, giving rise to the construct of autopoiesis (self-creation; Thompson, 2007) and the active learner (e.g., Bruner, 1960), as opposed to the passively conditioned learner (e.g., Watson, 1930). Cognitive strategy instruction in education is predicated on ideas from this thread.

The third strand, following from directions in psycholinguistics, took an ever-greater interest in the situational, contextual, and social factors involved in knowledge construction (as well as in the organic necessity, not just traditional theoretical preference, for parsimony in models of cognitive processing). This strand inspired greater interest in sociocognitive theories of learning that have proven especially appealing to educators.

Additional cognitive constructivist variants of note include *radical constructivism* (von Glasersfeld, 1990), a strong philosophical repudiation of any correspondence theory of truth; *neo-connectionism* (e.g., Elman et al., 1997), an application of so-called neural network modeling to the problem of concept development; and the externalization of knowledge construction via *social* (or institutional) *construction of knowledge* (Berger & Luckmann, 1966/1984). Among the more currently engaging issues in cognitive constructivism is the role of knowledge structure formation in comprehension and its occlusion, the relationship of knowledge construction to consciousness, and the relationship of both to experience and language development (Tomasello, 2005).

Cognitive constructivism's structuralist and often computationalist orientation puts it at odds with most poststructuralist semiotic theory and even with more recent neurologically informed bioecological theories of learning and development. The term is often used in

juxtaposition to the more friendly term *social constructivism* (often, in current usage, conflated as simply *constructivism*), a theoretical orientation more closely related to the anthropological assumptions of much qualitative research in applied linguistics. It would be erroneous, however, to read into this distinction a forced choice: Cognitive and other mental processes respond and develop in response to social processes, and vice versa. But this oppositional positioning underscores the historical importance of cognitive constructivism as a point of reference for the social sciences, and it has contributed more to our currently under-interrogated assumptions about knowledge and learning than we often acknowledge. Work in artificial intelligence, robotics, neuroscience, neurolinguistics, situated cognition, and education continues to make productive use of its many implications.

Cognitive Grammar

CARITA PARADIS

Introduction

Cognitive grammar (CG) is a relatively recent approach within the functional family of linguistic theories. It originated in the late 1970s but did not gather real momentum until the 1980s, with seminal publications such as Lakoff (1987) and Langacker (1987a), followed more recently by Talmy (2000), Croft and Cruse (2004), and Geeraerts and Cuyckens (2007). CG is not a static monolith but a vibrant enterprise constantly undergoing developments and improvement. However, all work within the theory relies on some foundational assumptions shared by the members of the community. CG describes language as a structured collection of meaningful categories, which are formed on the basis of our experiences of the world and which help us store and manage information: “a way of organizing knowledge that reflects the needs, interests and experiences of individuals and cultures” (Geeraerts & Cuyckens, 2007, p. 5). From this overall characterization, Geeraerts and Cuyckens identify three main tenets: (a) the primacy of semantics in linguistic analysis; (b) the encyclopedic nature of linguistic meaning; and (c) the perspectival nature of linguistic meaning, indicating that the world is not objectively reflected in language, but an image of the world seen through the lense of the language user. This entry reflects these three tenets in order and concludes with some remarks on the notion of *usage-based*, which is central within the framework. The importance of the idea that linguistic categories, like most categories, are prototype continua with core and peripheral members is a recurring theme throughout. All these aspects make CG special and different from other approaches to linguistics, both within the functional school of thought and outside it.

The Primacy of Meaning

Absolutely essential to the CG approach is the meaningful functioning of language in all its guises and all its uses in text and discourse. Such an approach promotes empirical methods which are geared to natural language usage. Language is a highly dynamic entity for which no absolute boundaries between the traditional areas of syntax, semantics, and pragmatics are assumed. Human language is shaped by the two main functions it serves: the *semiological function* and the *interactive function* (Langacker, 1998, p. 1). The semiological function is the mapping of meanings (conceptualizations) with linguistic forms in speech, writing, signs, and gestures. This is the symbolic nature of language from which the centrality of meaning for all linguistic concerns follows. In the literature, these symbolic structures are often referred to as form–meaning pairings. The interactive function, on the other hand, concerns the communicative side of language use as a social phenomenon, including aspects such as the function of providing information as well as expressing the speaker’s subjective stance and intersubjective awareness. Both the semiological and the interactive functions are crucial for the guiding idea that language use must be explained with reference to the underlying mental processes as well as with reference to the social and situational context.

2 COGNITIVE GRAMMAR

More specifically, we can say that linguistic meaning is both fostered and constrained by a number of factors. The first factor is what we know about the world around, that is, encyclopedic knowledge. The second factor is the conventionalized symbolic links between lexical items and concepts in language, such as *dog*/DOG, *have a bath* /ACTIVITY(BATH), *the long and the short of it*/THE SUMMARY OF THE MATTER. Third, linguistic meaning hinges on human cognitive processes, such as attention and categorization, which pervade every level of language use. In example (1) such construal operations are the processes that allow us to interpret the circumstances described as an event that might have resulted in a goal, in which case the football player is the agent and also the most prominent figure, while (2) is more likely to describe an incident where the ball figures prominently. Example (3) is a case of metonymization which selects the most important part of the body for the description of a good academic. Through metaphorization in (4), we are able to understand a theory by comparison with a building, and in (5) a binary contrast between *chaos* and *calm* is set up and focalized (Paradis, 2004, 2005, 2011; Paradis, Willners, & Jones, 2009; Oakley, 2009).

- (1) *The football player* hit the ball.
- (2) *This ball* hit the football player.
- (3) There are *lots of good heads* at this university.
- (4) The theoretical *foundation* is solid.
- (5) I prefer *chaos* to *calm*.

All linguistic expressions are profiled according to “frames” or “domain matrices,” such as “on a hike” or “at a restaurant.” Frames or domain matrices are systems of concepts, which are related in such a way that in order to interpret the individual concepts we have to understand the structure of the whole (Fillmore, 1982, p. 111; Ungerer & Schmid, 1996, pp. 214–16; Goldberg, 2006). All such factors are available to speakers as presupposed information in communication.

Like most linguistic categories, lexicon and grammar are not discrete entities but form a continuum from more substantial (contentful) meaning structures such as PEOPLE, ARTIFACTS, and EVENTS, to more schematic structures (configurations), such as PATH, SCALE, PART/WHOLE, and BOUNDEDNESS. In contrast to “lexical meanings,” which are contentful and conceptually rich (e.g., “car,” “Africa,” “swim”), grammatical meanings rely mainly on highly schematic configurations such as “mass/count,” which is a BOUNDEDNESS configuration, and “temporality,” which may be viewed as PATH, that is, a timescale between past time and future time with “now” in the middle. The function of schematic categories also allows us to construe more complex expressions such as phrases and clauses and to ground them in the actual discourse situation. In between the two extremes are meanings such as negation, intensification, or meanings of prepositions, which are neither primarily contentful nor primarily configurational. Another important standpoint in some cognitive literature is that words and constructions do not “have” meanings (Cruse, 2002; Paradis, 2005, 2008). Meanings in language emerge from the contentful and configurational pre-meaning structures, which crystallize when they are used in human communication. The relation between pre-meanings and full discursive meanings is the same as that between the ingredients in a stew and the stew itself. They are two different substances. The pre-meaning stage can be illustrated using Figure 1. The way we see the human being in the picture can be compared to a certain pre-meaning stage. The ingredients that are present

Figure 1 A person heading somewhere © 2010 Olof Ekedahl. All rights reserved

in the picture form the basis of the emergence of the stew. The full meaning becomes clear when the pre-meaning is eventually properly couched in its situational context, just as the human being would have been, had she been focalized and set off against the background and the event.

The Linguistic–Encyclopedic Continuum

The second tenet concerns the encyclopedic nature of meaning in CG. This position is in stark contrast to the commonly held view among linguists of different persuasions that it is possible to make a clear distinction between linguistic knowledge and nonlinguistic or encyclopedic knowledge. This position is questioned by cognitive linguists. That an interpretation of an expression comprises both linguistic and encyclopedic knowledge is not controversial in any linguistic framework. A more controversial question is what the knowledge is like that is needed for interpreting sentences (linguistic knowledge) and what the knowledge is like that is considered superfluous for that purpose (encyclopedic knowledge), and where the dividing line between the two is located. Instead, the two types of knowledge are considered to form a continuum. Consider examples (6), (7), and (8) from Paradis (2003) from the point of view of the alleged divide between linguistic meaning and encyclopedic meaning.

- (6) Pubs *open* at 11.
Three hundred pubs *open* today.

- (7) We always make *fast* decisions.
 I dislike *fast* food.
 Angela is a *fast* writer.
- (8) The *newspaper* is on the kitchen table.
 The *newspaper* made ten journalists redundant.

The claim in CG is that knowing the meaning of *open* in (6), *fast* in (7), or *newspaper* in (8) always involves knowing about the kinds of activities one performs when one “opens things” such as pubs, boxes, debates, computer files, or books, or how various time specifications, such as “at 11” or “today,” influence the interpretation of *open*. In (7) and (8), we may ask ourselves what entities can be “fast” and in what way, and whether “newspapers” are artifacts, companies, or even people who work for the newspaper (Taylor, 2000, p. 121; Paradis, 2004). As pointed out earlier, it is not possible to fully understand the meanings of those words without knowing about the “frames” or “domain matrices” which they form part of. It is not possible to strip off what would be encyclopedic meaning because there is no way that we can know where to start and where to stop.

Although meaning in CG is encyclopedic in the sense that there is no delimited linguistic meaning, not all aspects of meaning are considered to be of equal status. Langacker (1987a, pp. 158–61) deals with such matters as gradation in terms of four *centrality* factors. The centrality of a certain specification is a matter of its relative sociocognitive entrenchment and likelihood of activation. Centrality correlates with the degree to which a specification is *conventional*, *generic*, *intrinsic*, and *characteristic*. Langacker uses *banana* as an example. His knowledge of *banana* includes the fact that his sister put sliced bananas on her cereal for breakfast in the morning, but this fact cannot be an aspect that is in other people’s minds and cannot be on a par with essential properties such as ontological type, size, shape, smell, taste, and color. Some specifications are not possible to omit, while others are completely irrelevant for even the most exhaustive description. This entails that not all aspects of our knowledge of an entity should at all times be taken into consideration. Language users always select relevant parts and focus their attention on those parts. What is important to accept is that lexical meanings involve all kinds of specification that we use in different communicative situations. This position is provocatively formulated by Jackendoff, who is, strictly speaking, not a cognitive linguist but shares many ideas with them:

Recall again what a word is: a way of associating units from distinct levels of representation. Now consider what it takes to be able to look at food and know what it tastes like: a learned association between a visual and a gustatory representation. How many of those do we store? A lot, I should think. From a formal point of view these associations of representations are not unlike those between phonological and conceptual structures. And as far as learning goes, they’re almost as arbitrary as word–meaning associations. Mashed potatoes and French vanilla ice cream don’t look that different. (Jackendoff, 1997, p. 107)

Perspectives and Construals

The third tenet concerns the fundamental idea within CG that linguistic meaning is perspectival and reflects language users’ capacity for conceptualizing the same situation in different ways. There is no completely neutral or indeed objective way of seeing, describing, and understanding a situation. Meaning in language is grounded and constrained by

how human beings perceive the world, and we express ourselves accordingly. In their introductory textbook, Radden and Dirven (2007, p. xi) give an expressive example of how language interacts with perception and attention. They say that if we see a bird flying above us, we focus on the bird with the sky as the backdrop and describe the situation accordingly as *a bird in the sky*. We do not focus on the sky and describe the situation as *the sky around the bird*. If we play around with one of the examples in (6) *Pubs open at 11* and change it into *The pubs open at 11*, we create an image of a number of specific pubs, as opposed to pubs in general. For visualizations of the difference between the two types, see Radden and Dirven (2007, pp. 89, 106). Grammatical constructions are always semantically motivated. Linguistic meanings are also grounded in social interaction. Meaning is constantly negotiated by us as language users on the basis of our intentions and our assessment of our and other people's knowledge of the world. Language unavoidably shapes thought, which entails some level of linguistic relativity.

Ways-of-seeing are crucial in language use and meaning making, whether they concern more contentful meanings such as nominal or verbal meanings, or sentences and discourses, or more schematic grammatical meanings such as tense and aspect (e.g., parts of speech in Paradis, 2005; transitivity in sentences in Langacker, 2006, Davidse & Heyvaert, 2008, and Paradis, 2009; or discourse phenomena in Talmy, 2000, and Oakley, 2009). In what follows, two concrete examples are given to illustrate the understanding of grammatical notions such as parts of speech and degree in language within CG. Parts of speech are defined as notional categories in most linguistic approaches; that is, nouns denote entities, verbs denote actions, and adjectives denote qualities or properties in the world. This entails that category membership is unambiguous and based on necessary and sufficient features, and such categories do not have internal structure in terms of centrality. There are obvious problems with clear-cut categories both from the point of view of the nature of linguistic meaning and from a methodological perspective. Typological studies of word classes (Dixon, 1982; Givón, 1984; Thompson, 1988; Wierzbicka, 1986; Croft, 1990, 2001; Stassen, 1997; Aikhenvald, 2000; Dixon & Aikhenvald, 2009) reveal that the categorization of forms into grammatical classes such as parts of speech is not a trivial matter. There is considerable consensus among typologists that the category of noun is a universal category, while the category of adjective is not. Givón (1979, p. 13) says that "The category of adjective is a notorious swing-category in language." English adjectives are a case in point with members that are rich conceptualizations, such as *American*, *economic*, and *fruity*, and members that are mainly configurational single property concepts, such as *mere*, *only*, and *main* (Paradis, 2005, pp. 554–60).

Langacker (1987b) proposes a part-of-speech model where a noun is viewed as *THING*, construed as an atomic notion conceived as static and holistic. Nouns are summary scanned, which means that all aspects of the concept are available at the same time and together form a gestalt. Verbs are conceptually *PROCESSES*. They are relational and sequentially scanned over time. Adjectives are similar to both nouns and verbs. They are relational like verbs, but they differ from verbs in being atemporal instead of temporal and summary scanned like nouns instead of being sequentially scanned like verbs. Langacker (1999, p. 11) gives *yellow* as a concrete example to illustrate the crucial function of construal in the classification of parts of speech. The conceptual content of *yellow* in the color domain is kept constant over its various construals into different parts of speech. *Yellow* as a noun, as in *yellow is a warm color*, profiles a particular kind of *THING* in color space. *Yellow* as an adjective, as in *yellow paper*, profiles an *ATEMPORAL RELATION* of a color sensation to a *THING*. *Yellow* as a verb, as in *the paper yellowed*, profiles a *PROCESS* in which the color of the *THING (PAPER)* gradually changes. Furthermore, Langacker contrasts the verbal sense, which profiles a sequential *PROCESS*, with the stative-adjectival meaning of the participle *yellowed (the yellowed paper)*. The verb and the participle evoke the same content. In fact,

the process profiled by the verb serves as the base for the participle in that something can only be yellowed if it has undergone a process of yellowing. The participle profiles only the final state, which makes it atemporal and nonverbal. The upshot of this story, then, is that it is the speaker who construes some content in the act of communication, and parts of speech are configuration construals. The speaker's choice of construal depends on how the message is best visualized.

Another, linguistic notion that is traditionally thought of as a grammatical notion is DEGREE. Most other linguistic frameworks would say that DEGREE is a grammatical notion related to the comparability of adjectives and adverbs and expressed through adverbs (*more, very*) and quantifiers (*much, all, a lot of*). However, there are also scholars who note that manifestations of DEGREE are, in fact, associated with more contentful categories such as nouns, verbs, and adjectives too (Sapir, 1949; Bolinger, 1972; Paradis, 1997, 2001). In particular, Paradis (2008) takes issue with the grammatical-class approach, which cannot account for the flexibility with which DEGREE is used and the apparent ease with which it is invoked in new contexts, and shows that it is first and foremost a configurational meaning structure that combines with structures pertaining to all kinds of knowledge: THINGS, EVENTS, and STATES.

Linguistic items that are primarily expressions of DEGREE, and linguistic items whose content has an underlying DEGREE configuration form a continuum. The notion of DEGREE may be foregrounded and construed as the most salient component of a meaning structure, or it may be construed as a backgrounded meaning structure. For instance, DEGREE modifiers such as *very, a bit, little, much, and totally* foreground DEGREE. In contrast to them, linguistic expressions, such as *bad, dead, adore, and beauty* foreground content structures such as MERIT, EXISTENCE, MENTAL STATE, and APPEARANCE respectively, while DEGREE resides in the background. For instance, while the meaning of *bad* is construed according to an UNBOUNDED SCALE configuration, *bad-good*, it primarily profiles the property of MERIT when it is used in language. There are many linguistic expressions that at first sight do not appear to be associated with grading, such as *man* or *book*, but may in many occurrences of use highlight properties that are gradable. For instance, the profiling of *a handsome man* involves the evaluation of a property of MAN along a gradable dimension of BEAUTY. Similarly, the profiling of *a marvelous book* involves a gradable dimension of BOOK as being "a good read" or "a beautiful artifact." The backgrounded DEGREE structures of such meanings provide the necessary condition for combination with degree modifiers, either directly as in *very nice, absolutely excellent, quite a man, and badly needed*, or as in *a very good book* through a gradable property of a BOOK (THING) bridged by "merit," as here specified by *good*. On a more creative note, there was a car advertisement in Sweden, *How WE are you? The new V70. Very WE*, where the personal pronoun *we* was used as something you can be more or less of. All this goes to show that DEGREE is not confined to the meanings of certain grammatical function words but is part of the use potential of a wide range of lexical items.

A Usage-Based Approach

Finally, the notion of CG being a usage-based theory, mentioned in passing at the beginning of this entry, merits more attention and qualification, since the term is ambiguous and may refer to two different but related things, which are both central to the framework. First, research within the framework is usage-based in the sense that it makes use of both textual and behavioral data sources. CG encourages empirical investigations using data from "real" language (Gonzalez-Marquez, Mittelberg, Coulson, & Spivey, 2007; Gilquin & Gries, 2009; Paradis et al., 2009). The other meaning of the notion of usage-based theory is with reference to how languages are acquired, how they develop, and how they change

in the contexts where they are used in social communication (Tomasello, 2003, 2008; Traugott & Dasher, 2002). Motivations for linguistic development and language change are always functional and spring from language use and communicative needs in the settings of the symbolic structures, that is, the conventionalized form–meaning pairings (Paradis, 2008, 2011). Different readings in different contexts emerge from the speaker’s intention and the addressee’s wish to interpret an expression in a relevant way in order to obtain socially viable mappings between words and concepts. Some of these uses lead to change while others are just contextualized shifts. Construal operations are the source of all readings, both conventional and ad hoc contextual ones, and possible lexical change takes place when new conventional, entrenched links between linguistic expressions and conceptual structures are formed. CG always seeks semantic motivations for grammatical construals. One major advantage of CG over other theories is that it has the tools to account for the dynamics of language use and meaning-making.

Cognitive Linguistics of Second Language Acquisition

MARJOLIJN VERSPOOR AND FRANK BOERS

Introduction

When investigating second language development or deciding on ways to teach it, it is important to know how language and language development are viewed in general, because it will determine to a great extent what you look for, what you find, and what you teach. For example, if you think that syntax (form) drives a modular system, your attention will focus mainly on form. On the other hand, if you think the need to communicate and express meaning drives a dynamic, complex system, your attention turns to how language users develop their meaning system and how insights into this development may help in teaching an L2. Cognitive linguistics (CL) holds the latter view. In this entry, we will first explain the basic concepts in CL, contrast them with syntax-driven approaches to SLA, and finally show how CL insights may be applied in the L2 classroom.

Origins and Central Tenets of Cognitive Linguistics

Before outlining its applications in the field of second language acquisition, it is useful to trace the origins of cognitive linguistics as a theory and to sum up some of its central tenets.

Cognitive linguistics (henceforth CL) began in the early 1980s, mostly as a reaction to generative, Chomskyan accounts of language. The founders of the CL movement felt that generative linguists described language too much as if it were an independent module in the mind. The alternative proposed by CL is to consider language as a reflection of general cognitive abilities and social interaction, i.e., mechanisms at work outside the realm of language. To CL advocates, language is thus an integral part of human cognition, not a distinct module. Diverse linguistic phenomena reflect human perception, human categorization, and human analogical and associative thought. Let's briefly illustrate each of these in turn.

The way messages are commonly packaged reflects the way people perceive reality. For instance, a moving entity (e.g., a big bird flying over our heads) will draw our attention to the effect that the background (e.g., patches of cloud in the sky) will be noticed less. This "figure-ground" experience, where the figure is the entity that gets our attention first, is reflected in the way that it is typically assigned a prominent role in an utterance, such as the subject of an active sentence. For example, *the children were running around the table* would appear a much more "natural" description of the scene than *the table was being run around by the children*. When language mimics reality, it is said to be "iconic." Well-known examples of iconicity are words that mimic sounds (so-called onomatopoeia), such as a cat's *meowing*, and standardized phrases whose word order mimics the chronology in which events normally occur, such as *stumble and fall* and *crash and burn*. However, CL theorists adopt a broader view of iconicity than most other linguists, who tend to have a

firmer belief in the arbitrariness of the sign (a conviction that harks back to the teachings by Saussure, the famous French structuralist).

Much of language reflects human categorization processes. Rather than seeing the world as a collection of distinct, neatly organized entities that are waiting to be named by humans, CL holds that humans impose their own categories on their world in a way that is relevant to them. That is why CL is said to take an experientialist perspective on human categorization. Communities may differ in the way they conventionally categorize things, however, and these differences are reflected in their lexicons. For instance, some communities may have a finer-grained categorization of the color spectrum than others, and consequently have more color terms at their disposal. At the same time, we can use one and the same word to refer to a variety of entities as long as we perceive these diverse entities as members of the same category. Inclusion in a category will often depend on the degree of resemblance to what is felt to be a “best” example of the category, a so-called prototype. For example, ostriches may be nontypical birds (at least to Europeans), but they are nevertheless called *birds* because of their resemblance to the prototype (which to most Europeans will look more like a tit or a robin) is felt to be sufficient. But the prototype at the center of a category may differ from one community to the next. For example, in Europe the prompt *fruit* is likely to elicit *apple* or *orange* as examples that first come to mind. In some other parts of the world such as India or South America, it might prompt *mango* or *banana*. These variations are due to the differing availability of these fruits in the respective communities. Less central members of the fruit category would be watermelons (much bigger than the prototype). A borderline case would be tomatoes (neither sweet nor sour, unlike the prototype), which many people would include in the category denoted by the word *vegetable* instead. It is with reference to “peripheral” members of a category that the referential scope of seemingly equivalent words is likely to differ from one language to the other. It is also with reference to peripheral members that the common denominator will often require specification to avoid misunderstanding: When we meet the word *mother*, we will be inclined to assume that this refers to what we consider to be the prototypical mother, i.e., the woman who gave birth to the child and who nurtures it, unless the referent is specified as *biological mother* or as *stepmother*. The *mother* example also illustrates how an utterance activates much more knowledge—crucially, *extralinguistic* knowledge—than what is actually “in the words.” Interpreting the word *alimony*, for instance, activates knowledge of a whole scenario (a so-called frame) involving two people getting married, having one or more children, getting divorced, and so on. It is thanks to the automatic activation of so much knowledge of the social as well as the physical world that utterances are functional despite their underspecification: The interconnectedness with acquired world knowledge allows language use to be economical.

Particular attention in CL has been devoted to standardized *figurative* language, and how figures of speech such as metaphor and metonymy reflect the basic cognitive abilities of analogy and association, respectively. For example, in English and many other languages, we can see expressions such as *she has a high position*, which means she has power and status, whereas *he has a low position* means the opposite. Other positive expressions are *the good news gave me a lift*, whereas negative expressions are *these problems are getting me down*. The fact that metaphoric uses of *up* and *high* often refer to something positive and *down* and *low* to something negative is likely due to an analogy with physical, bodily experience. When humans are standing upright, they tend to be fit, alert, confident, and mobile, whereas if they are stooping or lying down, they may be ill, weak, submissive, or in hiding. The thesis that a lot of language is grounded in bodily experience like this is called the embodiment thesis. Other figurative expressions that are “embodied” are related to emotions, such as anger as in *she was fuming* and *she just exploded*. When people are angry they often feel hot and become red in the face. This sensation or impression of increasing heat inside

the body invites an analogy with what happens to the content of a container (e.g., a kettle) if it is heated up. Metaphor enables us to describe intangible sensations and abstract concepts via analogies with more concrete and better understood experience. Another very common figure of speech is metonymy, which, rather than exploiting analogy, relies on our cognitive ability for association. For instance, in the utterance *there's been no comment from The White House yet*, the place-name stands for "the President of the US and his spokesmen or spokeswomen." Metonymy, as a reflection of our associative abilities, can thus serve purposes of economy again.

Observations that language and general cognition were found to be inseparable were made in the 1970s and 1980s by scholars such as Wallace Chafe, Charles Fillmore, George Lakoff, Ronald Langacker, and Leonard Talmy, who laid the foundation of the school of thought now known as cognitive linguistics. For more information on the roots of CL and its branches (such as frame semantics, conceptual metaphor theory, space grammar and force dynamics), see the official CL Web site: <http://www.cognitivelinguistics.org/cl.shtml>

An important consequence of seeing language as a reflection of general cognitive abilities is that many linguistic phenomena can be "motivated," i.e., they are explainable, albeit retrospectively. As we have seen, the way messages are conventionally packaged may be more iconic than has long been assumed; the way in which a single word or a single expression develops various meanings and usages can often be accounted for through associative and analogical thought, and so on. Further below, we will show that it is the exploitation of this notion of "motivation" that is a distinguishing feature of CL-oriented language pedagogy.

First, however, we need to outline the CL views of first and second language acquisition in general.

CL Views of First and Second Language Acquisition

The CL movement rejects the generativist postulation of a "universal grammar" with a "language acquisition device" and "innate grammar." According to CL, language acquisition (and language change more generally) is "usage-based." This means that L1 is acquired through exposure to and use of the language in social interaction. Children gradually master the language through imitation, analogy, hypothesis-testing, and generalization. It is this stance on language acquisition that has in recent years helped CL theorists forge an alliance with several psycholinguists (see Robinson & Ellis 2008 and Pütz & Sicola 2010 for collective volumes representing this alliance) who support the thesis that children's mastery of their mother tongue gradually "emerges" from exposure to language samples, interactive use of what they pick up from those samples, and their hypothesis-testing abilities. There is thus no need to postulate the existence of an innate, special-purpose grammar blueprint. How fast and how well certain language elements or patterns are picked up can be accounted for with reference to the interplay of several variables, including the frequency with which the element or pattern is encountered, its prominence in the input (e.g., its phonetic salience), and the transparency and reliability of its form–meaning correspondence. Prototypical usages of words and patterns are established as children encounter these early and repeatedly.

The same variables come into play in second language acquisition, but at least one variable is added. Unless the L2 acquisition starts at a very young age, the learners will have adopted "thinking-for-speaking" habits that are typical of their L1. Insofar as these habits overlap with those of the L2 this will be helpful, but insofar as they diverge this will be a hindrance. Especially older L2 learners have strongly entrenched L1 patterns and conceptualizations, which may transfer to the L2 (see Verspoor, 2008; Lowie, Verspoor, &

Seton, 2010). An additional difference from L1 acquisition concerns the distributional properties of the input. The discourse used among adults is “richer” than that used by carers to address children, and so more variants of a given pattern may compete for the learner’s attention. Input that is initially biased in favor of the high-frequency, prototypical usage of a pattern has been shown to facilitate early acquisition of that pattern.

Another point of convergence of CL proponents and like-minded psycholinguists is their rejection of the view that language is made up of a lexicon and a set of grammar rules. This simplistic dichotomy is replaced by the view of language as a continuum from small elements to complex patterns. All of these, irrespective of their size, are now commonly called “constructions” in CL jargon (e.g., Goldberg, 2006). This includes concrete and particular units such as morphemes, words, and idioms as well as more abstract or schematic units such as word classes and sentence patterns. Language learning is thus construction learning at various levels of linguistic complexity, and it is no longer viewed simply as vocabulary + grammar-rule learning. This conception of language as an inventory of units ranging from simple to complex ones also draws semifixed multiword units (such as idiomatic expressions and strong collocations) into the spotlight. In this respect, at least, the CL movement is in agreement with several applied linguists who have in recent years made a case for phraseology-oriented language pedagogy (see Boers & Lindstromberg, 2009 for a review).

The view of second language acquisition as a usage-based, dynamic process that is in many ways similar to L1 acquisition entails that learners benefit from receiving a lot of meaningful input from which to pick up elements and patterns for imitation, extension, and generalization. It also entails the need for opportunities for hypothesis-testing through output in meaningful social interaction.

High quantities of input and ample opportunities for output are available in contexts of “naturalistic” learning, that is, when learners spend a long time in the L2 environment, for example as young immigrants or as students in an immersion program. A substantial amount of second language learning takes place in a more “formal” setting, however, typically at school, college, or university, where exposure to and use of the L2 are much less self-evident. It is concerning those learning contexts, also called *instructed* second language acquisition, that most proposals for pedagogical applications of CL have been put forward. We will turn to these next.

CL Approaches to Instructed Second Language Acquisition: General Rationale

CL-inspired proposals for language pedagogy typically draw from case studies in which the motivated nature of language is highlighted. Students of English as a second language can be helped to appreciate, for example, that the meaning of expressions such as *time flies*, *(being) behind schedule* and *(being) ahead of time* is not at all accidental, but rather the reflection of one of the ways in which we conceive of the intangible notion of time—that is, the conception of time as a moving entity (and us trying to keep up with it). Learners have indeed been shown to find it easier to guess the abstract sense of a word such as *forge*, as in *forge an alliance*, after they have learned its literal sense (as in *forge a sword*). Moreover, they are also likely to remember it better (Boers, 2000; Verspoor & Lowie, 2003).

The idea that learners will benefit from recognizing the motivated nature of L2 target elements rests on the premise that insightful learning (as opposed to blind memorization) fosters the formation of durable traces in memory. This premise is at the heart of general models of memory, such as the levels-of-processing hypothesis (Cermak & Craik, 1979) and the dual coding hypothesis (Paivio, 1986), and they are fully compatible with models

of memory proposed in the field of second language acquisition in particular, such as the noticing hypothesis (Schmidt, 1990). In the domain of second language vocabulary acquisition, for example, it is believed that the degree of engagement of a learner with a given target item is one of the determining factors in how fast and how well that item is added to the learner's L2 repertoire (see Schmitt 2008 for a review of research on L2 vocabulary acquisition). In what follows we offer a synopsis of ways in which pedagogy-oriented CL has proposed to turn various types of linguistic motivation into channels for cognitive engagement.

CL-Inspired Ways of Teaching L2 Words and Expressions

Most proposals for CL pedagogical applications target L2 words and expressions and they aim to stimulate insightful learning by raising learners' awareness of the motivated connections between the diverse meanings that a word or expression has developed (radiating from a prototypical usage). Several such proposals and experimental evidence of their effectiveness can be found in Achard and Niemeier (2004), Boers and Lindstromberg (2008) and De Knop, Boers, and De Rycker (2010).

For example, the meaning of *beyond* in *Why she left such a good husband is beyond me* and *He had changed beyond recognition* can be explained to students by connecting it to a more literal usage of this preposition, as in *The cat was sitting beyond the reach of the chained dog*, and by pointing out the commonness of the figuration (in this case the conceptual metaphor ABSTRACT INACCESSIBILITY IS DISTANCE), which is noticeable also in *That's far from clear to me* and *It didn't even look remotely familiar*. Quite often in CL pedagogy, schematic drawings are used to elucidate the literal usage of a preposition. Also the use of prepositions and adverbs when they are used as part of phrasal verbs can be shown to be nonarbitrary to the language learner. For example, the meaning of *out* in *She's found out about my affair* and *The exam turned out quite easy* may be clarified with reference to the conceptual metaphor KNOWING IS SEEING (the commonness of which can be demonstrated by means of the example *I see what you mean*) and the inference that what is outside a container is likely to be visible.

Motivated connections between literal and figurative meanings can also be pointed out to language learners with regard to the figurative usage of so-called manner-of-motion verbs (as in *Inflation was soaring*, *Holmes stumbled on a piece of evidence* and *The PM dodged all questions about the war*) (e.g., Lindstromberg & Boers, 2005). These are known to be notoriously difficult for learners whose L1 belongs to a type of language that makes comparatively little use of such verbs (e.g., Slobin, 2000; Cadierno, 2004).

It has also been proposed that learners can be helped to master so-called grammaticalized words by reminding them of the earlier, lexical uses. A simple example is *going to* as a marker of the future (e.g., *I'm going to buy her a bouquet of roses*), which can be motivated as an extension from the literal, spatial sense of the verb (e.g., *I'm going to the florist's*). The causal use of *since*, as in *I couldn't drive since I'd been drinking*, can be motivated as an extension via inferences from its temporal sense, as in *She's been feeling fragile (ever) since she had that accident*.

Figurative idioms have been a particularly popular target for CL-inspired pedagogy. Proposals range from systematically grouping idioms according to the metaphor themes they happen to instantiate (for example, *being hot under the collar*, *blowing off steam*, *breathing fire* and *adding fuel to the fire* can be grouped under the metaphor ANGER IS HEAT) or the common domain they happen to have originated from (for example, *taking something on board*, *showing someone the ropes*, *being on an even keel*, and *being in the doldrums* can be grouped as expressions generated by the domain of seafaring) to the occasional resuscitation

of the literal reading of an idiom as it happens to occur in a text used in the classroom (by pointing out to students, for example, that *behind the scenes* can have a literal meaning in the theatre and that *being on the ropes* can have a literal meaning in boxing). Pictures or drawings depicting the literal usage of the expressions may be added for purposes of elucidation or consolidation. For example, the literal reading of *in the wake of* . . . can easily be elucidated by drawing a ship and the waves it generates as it moves ahead.

All of the above-mentioned interventions stimulate “semantic elaboration,” i.e., the creation of associations concerning the *meaning* of the target words and expressions. According to some studies on vocabulary acquisition (e.g., Barcroft, 2002), this does little to aid retention of the *form* of the items. Pathways for form-focused elaboration have been explored in recent years by Lindstromberg and Boers (2008), who point to the high incidence of nonarbitrary phonological repetition (e.g., alliteration) in the formation of compounds (e.g., *bunk bed*), idioms (e.g., *from pillar to post*), collocations (e.g., *wage war*), and various other formulaic sequences (e.g., *last but not least*). Drawing learners’ attention to such sound patterns in L2 words and phrases has been shown to foster their recollection.

CL-Inspired Ways of Teaching L2 Grammar

Another strand of CL proposals for instructed second language acquisition deals with more “schematic” (i.e., abstract) targets for learning, which would conventionally be termed grammar topics (De Knop & De Rycker, 2008). For example, it has been suggested that spatial imagery be used to clarify the distinction between so-called continuous and simple tenses in English (e.g., *She was reading the letter* versus *She read the letter*), where continuous tenses are said to present an action or event as a zone without clear boundaries, while simple tenses present the action or event as a bounded zone. The same imagery can be applied to clarify the distinction between so-called uncountable and countable nouns (e.g., *much fog* versus *many clouds*). CL-inspired lessons on the English article system exploiting this notion of “boundedness” were developed and experimentally tested by Verspoor and Huong (2008).

Other recent CL proposals for grammar teaching target sentence patterns at a level of analysis that is less abstract than that of syntactic analyses. For example, *He pushed me out of the room* is a literal instance of the “caused-motion construction.” From such literal instances of a construction, more figurative extensions can develop. In *He stared me out of the room*, for example, the cause of the motion is no longer tangible. In *He was cheated out of his job*, both the cause and the location are abstract. The range of extensions available for each construction varies from one language to another. This is why instruction about L2 constructions may be helpful, because learners may erroneously transfer extensions available in their L1 to their use of the L2 or disregard the communicative potential of extensions which happen to be missing from their L1.

It has to be acknowledged, however, that as far as these CL proposals for grammar instruction are concerned, not much empirical evidence for their effectiveness has yet been attested.

CL-Inspired Ways of Raising Learners’ Crosslinguistic and Cross-Cultural Awareness

In the preceding sections we have given a synopsis of ways in which CL pedagogues propose to target distinct L2 elements (such as multimeaning words, figurative idioms, and constructions). In keeping with the CL tenet that language is intertwined with social experience, several pedagogy-oriented cognitive linguists have also suggested ways of

stimulating students' broader communicative competence by heightening their awareness of social and cultural variables of language use (e.g., Littlemore & Low, 2006). Comparative studies of figurative language (e.g., Kövecses, 2006) are one source of information for raising students' awareness of cross-cultural differences. For example, it may be an eye-opener to students from a Western background when they are informed that metaphorical references to the heart as the seat of the emotions and the head (or mind) as the seat of reason are not at all universally shared (e.g., Charteris-Black, 2002). Also the extent to which certain domains of life have permeated a community's figures of speech may vary from one community to another. For instance, speakers of Spanish have many more figurative idioms available to them that have originated from the domain of religion than speakers of English do and this also holds for the domain of bull fighting (Boers & Stengers, 2008). In an indirect way, the repertoire of figurative expressions of a given community may be considered as a reflection of its culture (albeit of the past). Students have been found to misinterpret L2 figurative utterances because of lack of familiarity with culture-specific metaphors and also because of cross-cultural differences regarding the value judgments associated with seemingly familiar ones (Littlemore, 2001). For example, depicting government as a machine (and ruling politicians as "technocrats") may be a common way of conveying a negative stance toward government in Western culture, but this value judgment may be absent from seemingly equivalent metaphors in other cultures.

Conclusion

The essence of a CL view of second language acquisition generally is that it is driven by the interplay of variables such as frequency (influencing prototype formation), saliency effects (influencing what elements in the input are noticed most easily) and the relative reliability of form–meaning correspondences (influencing the success of hypothesis-testing). In addition, it is likely to be affected by the learner's entrenched L1 habits. Special attention is given to the role of constructions at a level of complexity between single words and syntax.

The essence of CL-inspired second language *instruction* is that it fosters learners' appreciation of the nonarbitrary features of words, phrases and patterns that they are aiming to master. The benefits of the described interventions are believed to be brought about by the cognitive engagement they encourage on the part of the learner. In many of the interventions there is the additional likelihood that learners will associate the target expressions with mental pictures of concrete scenes. The results of a growing body of studies generally support the thesis that CL-type instruction is effective.

Cognitive Models of Interaction

ROBERT E. SANDERS

Cognitive models of interaction comprise ideas about the tacit knowledge or mental processing required to engage in social interaction. The knowledge and mental processing of interest is just what is required for two or more persons to alternately produce utterances and embodied actions that are interconnected with each other's, and thus are interactive. This does not include many of the diverse cognitions that persons also draw on when interacting, for example their knowledge about and attitudes toward the matter at hand; their knowledge about and attitudes toward each other; their identities and stereotypes; their roles, rights, and obligations; and their power relation and social status. These other cognitions may influence the content, outcome, and usefulness of an interaction, but are not essential to achieving interaction as such.

A variety of ideas about the cognitive basis for engaging in social interaction have been put forward. However, these have not always been presented under the heading of "cognitive models of interaction." Instead, many of them have developed independently, in relation to topics and issues within distinct subfields, principally conversation analysis, language pragmatics, discourse analysis, applied linguistics, communication theory, and artificial intelligence. Relevant work is bound together by its agreement on the first of the following propositions, and contention about the soundness and details of the second.

1. When two or more people interact—alternately producing utterances (or embodied actions)—not just any utterance (or embodied action) can meaningfully, coherently, or functionally be produced next.
2. There is a principled basis for constraints on what is produced next in an interaction that people must know consciously or tacitly in order to *interact*, to produce utterances (or embodied actions) that are responsive to those of others, and cohere with them productively in joint undertakings that bring about a co-constructed end result.

Sanders (1987) regards knowledge of the constraints on what is produced next within interactions as constituting a distinct "competence," an interactional competence. Levinson (2006) refers to such knowledge as constituting an "interaction engine." Both regard such knowledge as distinct from linguistic and sociocultural knowledge, in that pairs of people who do not speak the same language and are not natives of the same culture can still engage each other in coherent and productive social interactions, using improvised means of expression drawing on a relatively small repertoire of gestural and vocal universals.

Different formulations of the constraints on what is produced next have in common that it is a matter of what is or is not relevant—a matter of relevance to others' utterances or actions, or to the end result the parties may interactively bring about, but not relevance to the cognition of oneself or others, as in Sperber and Wilson's (1986) relevance theory. However, it is not a settled matter what the basis for such constraints is, or their generality, scope, and content. Different formulations of these constraints, and tacitly, different cognitive models of interaction, emerged mainly in the 1970s and 1980s. Work on them since may have been inhibited by the resistance among conversation analysts to premature theorizing. Most have proven sufficiently fruitful to have endured, and been applied and refined, without much concern for integrating them or going beyond them.

2 COGNITIVE MODELS OF INTERACTION

Proposed formulations vary along two main dimensions. One dimension involves their basis. Constraints on what is produced next may have a discursive basis involving meaning relations between temporally ordered utterances or embodied actions, and thus be principled and cross-situational. Alternately, such constraints may have a social basis—a relational, institutional, cultural, or practical basis—involving the functionality of utterances as means to ends, and thus be conventional, situated, and variable, rather than principled. Searle (1992) implicitly attributes constraints on what is produced next to custom and practicality, in that he acknowledges that not just anything can be produced next in an interaction, but contends that there are no (discursive) rules regarding this.

Another dimension along which ideas about these constraints vary involves their scope. They may apply just to the production of utterance or action pairs (or in some instances, triples), such as “complaint” (first part) and “apology” or “excuse” (second part), where a first part makes contingently relevant, and thus constrains, a second (and sometimes a third) part. Alternately, they may apply to the production of multiunit wholes, often internally organized with beginnings, middles, and ends, such as a service encounter, a job interview, or an information-gathering and planning discussion. Within such wholes, what is produced next may be constrained by its relevance to a pre-established end point, or to some thread that links prior components to form a whole, or both. In such wholes, the component utterances or embodied actions may be sequentially ordered and interdependent, and there may be well-formedness criteria. The resulting four broad possibilities—discursive constraints within whole sequences or between pairs, or social constraints within whole sequences or between pairs—are not mutually exclusive.

The concept of “adjacency pairs” is the most prominent formulation of constraints that apply to utterance pairs or triples. This particular concept of pair-wise constraints was developed by the conversation analysts Schegloff and Sacks in the 1960s and early 1970s (see Schegloff & Sacks, 1973). These constraints have a primarily discursive basis. The concept is that part of the meaning of some utterances is that they make certain responses contingently relevant, such as questions that make an answer relevant, or offers that make acceptance or rejection relevant. More than that, the contingent relevance of these responses makes the hearer’s failure to produce the response a marked omission or evasion. They thus not only discursively constrain what comes next, but create a social incentive for the hearer to produce it. What people need to know to interact on this basis is thus what the meaning of utterances is that function as first parts of adjacency pairs or triples. However, Schegloff and Sacks (1973) regarded such pairs as a special case of constraints on what comes next that is not broadly applicable. They regarded much of what comes next in an interaction as constrained instead on the basis of what would be topically relevant, and held that this is a much less restrictive constraint than the constraint produced by the first part of an adjacency pair.

The constraint produced by the first part of an adjacency pair on what comes next does not necessitate that the second pair part be produced immediately after the first, or produced at all. The other may not produce the second pair part (e.g., may not know the answer to the question or may not be willing to produce it), or there may be intervening utterances between the first and second pair parts—embedded sequences or side sequences. Someone who is asked a question may seek clarifications before answering it, and someone who receives an offer may seek further information about it before accepting or declining. As a result, there can be extended, internally structured, sequences comprising interwoven pairs of what Edmondson (1981) terms proffers and satisfactions, the whole bounded by an initial proffer and a terminal satisfaction. Reichman (1985) took note of the discourse markers within turns that signify a move into or out of embedded sequences, although she did not make claims about the organization and interconnections within such sequences.

Grice (1975, 1989) developed a quite different way of conceptualizing what can be

regarded as pair-wise constraints on what comes next. One key difference is that despite a number of his examples, he did not regard the constraint on what comes next as a product of a particular utterance, but rather a product of "the accepted purpose or direction of the talk exchange" (Grice, 1975, p. 45). This constraint can still be regarded as the product of a singular antecedent, but an antecedent produced by context and by prior utterances in concert rather than singly. Accordingly, this can also be regarded as a constraint that arises from the engagement of interacting people in a larger whole, the talk exchange. Moreover, on the one hand these constraints have a discursive basis. It is on the basis of what they are about, their semantics, that utterances are constrained by the purpose and direction of the talk exchange. On the other hand, the purpose or direction of the talk exchange is a contingent, social matter and thus these constraints also have a social basis. What people have to know to interact on this basis, then, is first, how to infer the direction or purpose of the talk exchange from relevant evidence (e.g., from the social context, and the utterances that have been produced so far), and second, how utterances are semantically interconnected to be congruent with and constructive of that direction or purpose. Grice is vague about these specifics, and much remains to be done to flesh them out.

A second, fundamental, way Grice's approach differs from the concept of adjacency pairs is that in Grice's view, constraints on what comes next do not delimit the particular utterances or utterance-types that come next, but rather, they delimit the interpretation of whatever comes next. In this view, if a question is asked, then whatever utterance is produced in the slot for an answer will be interpreted as an answer if at all possible (or else as a non sequitur produced to avoid answering), as long as it conforms to the accepted purpose or direction of the talk exchange to produce any answer at all. This accounts for the absence of answers when a question is interpretable as "rhetorical" (based on the question's relevance to the purpose and direction of the talk exchange), and if an answer to a rhetorical question is produced anyway, Grice's view accounts for interpretations of that answer as a mistake or sarcasm.

In contrast to the concept of constraints on what comes next based on what would be responsive to an utterance's or action's antecedent(s), there are concepts of constraints based on what is required of participants at each next turn to jointly produce some larger whole (e.g., a sales transaction), or interactively achieve some goal. An early approach from this perspective arose in artificial intelligence research, most notably the work of Schank and Abelson (1977) on such knowledge structures as scripts and schemas. These authors posited that in standardized contexts, there are conventional multistep procedures that are sequentially ordered (scripts), and interconnections among components (schemas). For example, in patronizing certain kinds of restaurant, customers are seated before they order, order before they are served, eat before they pay, and pay before they leave. Within such procedures, there clearly are constraints on what comes next. These constraints are not based on the discursive relation between components from one to the next. They are based instead on the practicality or functionality of each included action and their sequential order in collectively bringing about some end result. Hence, the ordering of the same components of patronizing a restaurant may vary with the type of restaurant. For example, in a fast food restaurant customers are seated after they order, are served after they pay, and leave without leave taking after they have eaten.

A different idea about constraints on what is produced next within multiunit wholes is that there is a principled, discursive basis for them. This stems from the view associated with the concept of a text grammar that linguistic objects combine in principled ways beyond the level of the sentence. Van Dijk (1980) developed this approach extensively, but with a focus on the meaningfulness of combinations of sentences (in texts) or actions (in interactions) to form macrostructures (e.g., a paragraph or episode) and superstructures (combinations of macrostructures). He considered that there are constraints on what is

produced next within such larger wholes, although spelling these out was not his concern:

for a sequence to be coherent not only the actions should be connected but they should also be *conceptually* related: Not wanting to read a linguistics book this afternoon may be a reason for going fishing, which is a necessary condition for the possible consequence of catching a fish, which may have my eating fish for dinner as a possible consequence. Yet, not wanting to study linguistics and having fish for supper are not conceptually related. In terms of the coherence conditions for discourse, we would say that they belong to different *topics* or *themes*. Hence, there must be a *global* constraint that makes action sequences coherent, and it is at this point where we need *macrostructures of action*. (van Dijk, 1980, p. 140)

Despite van Dijk's interest in extending the boundaries of linguistics to include such larger discourse and action wholes, the basis he posits on which their components are interconnected and constrained seems to be extralinguistic. It is a matter of the real-world, practical and functional relationships between objects and events that the parties refer to or act on. At the same time, in contrast to Schank and Abelson's (1977) approach, van Dijk's concept of the basis for constraints on what is produced next in larger wholes is not limited to standardized contexts.

Sanders (1987) proposed that there are both discursive and social constraints on what is produced next in interactions, and that these generally apply concurrently and congruently, but sometimes may conflict. He specified discursive constraints that arise from a "ground of coherence" that emerges between components of larger wholes as they are added to an unfolding sequence. A ground of coherence forms emergently as successive components are relevant to each other based on commonalities in their propositional content, or in the felicity conditions of the illocutionary acts they count as, or in what they implicate, or all of these. In addition, Sanders posited that there are constraints on what is produced next based on what is discursively relevant to a desired end result. While these latter constraints have a discursive basis (the meaning relations between components of the whole and the desired end result) they also have a social basis in that they arise from the participants' situated interest in achieving a certain outcome.

Levinson (1992) proposed a narrower, more precise, conception than van Dijk (1980) or Sanders (1987) of the larger wholes that constrain what is produced next and its interpretation. Levinson considered that persons interact within the framework of an activity that delimits what end results can be achieved and what actions are engaged in to achieve them. He roots this idea in Wittgenstein's (1953) concept of language game, and the concepts of speech events and episodes in ethnographies of speaking (Gumperz, 1972; Hymes, 1972). Levinson notes that activities range from "[a] totally prepackaged activity . . . [to] the largely unscripted event (e.g., a chance meeting on the street)" (1992, p. 69). This concept improves on, but is consistent with, much prior thinking. It provides a clearer basis for establishing the "purpose and direction of the talk exchange" than Grice (1975) gave, while retaining Grice's idea that components of interactions are interpreted relative to their contribution to the apparent purpose and direction of the talk exchange. The concept of activity is also consistent with Schank and Abelson's (1977) ideas of scripts and schemas, but applies much more comprehensively "to any culturally recognized activity" (Levinson, 1992, p. 69). The concept of activity is consistent, too, with van Dijk's (1980) concept of interactional superstructures, but it adds a basis external to and sometimes prior to the production of such superstructures, instead of van Dijk's tacit view that they are emergent as interactions progress. And the concept of activity is consistent with Sanders's (1987) view that interacting persons generally are constrained by the end result they are attempting to bring about, but improves on it in two ways. It specifies what the basis is of the

end results persons interact to bring about, and it provides for a greater restrictiveness on what is produced next than simply what is and is not discursively relevant to that desired end result.

Except for the concept of adjacency pairs, thinking about constraints on what is produced next in interactions has increasingly focused on the importance of the larger whole that participants are engaged in producing. In his summary of the key cognitive underpinnings of his "interaction engine," Levinson (2006) cites first, attributions to others of what might be termed "macro-intentions," and second, taking the perspective of the other on oneself and on the situation. Both of these can be tied to inferential processes about the current activity or larger whole the parties are engaged in producing. But from work so far, it is clear that constraints on what is produced next as interactions progress also arise from the discursive relations between components of the interaction. In this regard, Levinson (2006) cites the importance of reasoning along Gricean lines about the other's intention in having produced that component of the interaction just then, and therefore its meaning.

The path toward future development of cognitive models of interaction leads to two core tasks. One is to detail the knowledge base and inferential processes by which participants undertake to arrive at a mutual understanding of the larger whole which they are engaged in producing, especially when it is at the more implicit, more unscripted, end of the continuum of activity types. The other is to detail the bidirectional influence between the activity in which the parties are engaged and their production of and interpretation of the components of their interaction.

Cognitive Second Language Acquisition: Quantitative Methods

BILL VANPATTEN

Cognitive second language acquisition (SLA) research encompasses a wide variety of issues and phenomena, including, but not limited to, language processing (including sentence, discourse, and lexical processing), nonlinguistic factors affecting acquisition (e.g., aptitude, motivation), and instructed SLA (e.g., the effects of formal instruction on acquisition, the effects of task orientation on performance). In short, cognitive SLA research can refer to that which is not either purely linguistic or social in nature (“purely” suggesting that there can be overlap between the linguistic, the social, and the cognitive in some cases).

This entry will focus on instructed SLA and will illustrate the use of the *repeated measures analysis of variance* (ANOVA) design (although in cognitive SLA more generally a variety of designs can be used depending on the research question: *t* tests, ANOVA, ANCOVA (analysis of covariance), chi-square, and correlational analyses, among others). The repeated measures design is used in instructed SLA research because the researcher normally wants to see how an instructional treatment affects learning (e.g., Norris & Ortega, 2000). The researcher administers a pretest (Time 1) to the participants, delivers the treatment, and then administers a posttest (Time 2) or a series of posttests at different points (Time 2, Time 3, Time 4, and so on). If there is improvement from Time 1 to the subsequent test times, then the researcher can claim some kind of causative effect: The treatment under question had a positive effect. If there is no improvement, then the researcher would claim the treatment was not effective. If learners perform worse on the posttest(s), then the researcher might conclude the treatment had a negative effect.

Before research is conducted using a repeated measures ANOVA in instructed SLA, the following features of the design are typically present.

1. There must be at least one *treatment group* (called the *experimental group*) and one *control group*, the group that does not receive the treatment. A control group is necessary to ensure that any effects observed in the experimental group are indeed due to the treatment and not to improvement that would happen naturally over the course of time.
2. Participants are *randomly assigned* to treatment(s) and control.
3. The pretests and posttests must not be the same test but they must be of the same nature and be matched for level of difficulty. What researchers normally do is create various versions of a test (say, versions A and B) and then create a *split block* by which 50% of the participants receive version A as the pretest and 50% receive version B. Then the tests are switched for the posttest: The 50% that received version A receive version B and vice versa. In this way, any slight irregularities in the test are accounted for. What researchers should not do is give the experimental group version A and the control group version B and then switch: If there are irregularities in the test, they might create a difference between groups prior to the treatment.

We will now illustrate a classic repeated measures design. The point of this exemplary study is to compare the effects of processing instruction (PI) on three different kinds of

measures: (a) a sentence-level interpretation task; and (b) two production tasks—a sentence-level production task and a short discourse-level reconstruction task (see VanPatten & Uludag, 2011, for the original study). The question the authors are asking is whether the effects of PI (a specific input-oriented and sentence-level treatment) transfer to tasks not part of the treatment (in this case, the two production tasks). The following are the elements of the design.

- There were two groups: one experimental (the PI group) and a control group that did not receive treatment. Participants were randomly assigned to each group.
- The target structure was the English passive.
- The participants were adult first language (L1) speakers of Turkish learning English as a foreign language at the university level.
- There were three tests: a pretest, and two posttests. The latter were administered immediately after treatment and then two weeks later. The tests consisted of an interpretation test (to see whether participants could correctly determine who did what to whom), a sentence-level production test (written), and a reconstruction test (in which participants heard a short, 25–30-word passage, and then had to reconstruct it in writing). The first test was designed to bias for the PI group (PI participants engaged in this kind of task during treatment). The other two tasks did not form part of the treatment and were “novel” tasks vis-à-vis the grammatical structure and processing problem that was the focus of the treatment.

After the researchers scored the data, they entered it into the statistics software *SPSS*. Figure 1 displays this data entry. Column 1 contains the Group identifier: 1.00 = PI; 2.00 = Control. The next three columns represent the scores on the interpretation test: column 2 = pretest (PreInt), column 3 = posttest 1 (Post1Int), and column 4 = posttest 2 (Post2Int). The subsequent three columns represent the scores on the sentence-level production test (pretest, posttest 1 and posttest 2, respectively), and the final three columns represent the scores on the reconstruction test (again, pretest, posttest 1, and posttest 2, respectively). Note: data were originally scored and entered into an Excel sheet and then imported directly into *SPSS* using the import function.

Before running the repeated measures ANOVA, the researchers had to ensure that there were no significant differences on scores on the pretest (i.e., that all groups were performing at the same level prior to treatment). Thus, the researchers ran three *one-way ANOVAs* on each of the pretests: interpretation, reconstruction, and sentence-level. To run an ANOVA in *SPSS*, we click on Analyze, then on Compare Means, and then on One-way ANOVA (Figure 2). A dialogue box appears, asking us to indicate our within- and between-group factors. We click on PreInt and then the arrow to move it to within-subjects factor, and we click on Group and then the arrow to move it to between-subjects factor (Figure 3).

For illustrative purposes, we will use only the interpretation part of the output (Figure 4). The part of the output to focus on is Group. In reading this line, we see no difference between PI and Control, as seen by the *F value* and the *p value* (represented by “Sig.” in the output of the *SPSS*). In a research paper, we would report it this way: “The one-way ANOVA on the interpretation pretest scores revealed no main effect for Group, $F(1, 37) = 2.028$, $p = .163$.”

Next, the researchers ran the repeated measures ANOVA for each of the three measurement types. Again, for illustrative purposes, we will use only the data from the interpretation test here. To run a repeated measures ANOVA in *SPSS*, the researcher clicks on Analyze, then on General Linear Model, and then on Repeated Measures (Figure 5). A dialogue box appears in which the researcher has to indicate the name of the within-subjects factor and how many levels it has. For this study, we type Interpretation to replace

Figure 1 SPSS data set for the study on PI and transfer effects
Note: there are 38 participants split across two screens.

“factor 1” and then in the levels box we type “3” (to indicate that there are three interpretation tests). These steps and the results are displayed in Figure 6. Next, we click “Define” and a new dialogue box opens up. Here we have to tell SPSS which three tests are the within-subjects factor so we click on PreInt and click the arrow to move it over to the right side. We do the same for Post1Int and Post2Int. Then we have to tell SPSS which variable is the between-subjects factor. In this case, it is Group so we click on that, click on the arrow, and move it over to the right. This is all we need for the present study so we click “OK” (Figure 7).

Figure 2 Navigation to one-way ANOVA

Figure 3 Dialogue box for one-way ANOVA

The output of the repeated measures ANOVA appears in Figure 8. There are two parts of the output to examine: the Test of *Between-Subjects* Effects (which tells us about PI vs. Control) and the Test of *Within-Subjects* Effects (which tells us about the Interpretation tests over time and any possible interaction with the between-subjects factor, Group). As can be seen, Group makes a difference, with the F value 41.274 and the p (sig.) value .000. At the same time there was an effect for Interpretation, as can be seen in the F value, 47.602, and the p value, .000. Importantly, there was no interaction between the two variables of Group and Interpretation (see the line Interpretation * Group): F value is 38.551, p value is .000. We would report these results in the following way: “The repeated measures ANOVA on the interpretation tests yielded a main effect for Group, $F(1, 37) = 41.274, p = .000$,

Figure 6 Dialogue boxes for setting up repeated measures ANOVA

Figure 7 Dialogue boxes for inserting variables into repeated measures ANOVA

However, we are not finished with probing our interaction. We must also probe the effect for Interpretation. In this case, we must conduct a series of *paired-samples t tests* for the PI group comparing the following: pretest versus posttest 1, posttest 1 versus posttest 2, and pretest versus posttest 2. We must do the same for Control. First, we separate out the PI and the Control data into two different data sets (in the present example, we cut Control from the data set and pasted it into its own data set). To conduct a *t* test in SPSS on the PI data, we click on Analyze, then Compare Means, and then click on Paired Samples T Test (“paired” because we are comparing means from the same group, not means from different groups). A dialogue box appears and we must click on the scores we want to compare. First, we click on PreInt and then the arrow. This inserts PreInt into one slot on

Figure 8 Parts of the SPSS output for repeated measures ANOVA on interpretation test

the right side. Then we click on Post1Int and then the arrow. This inserts Post1Int next to PreInt, indicating SPSS will compare these two scores with a *t* test. We continue with our other comparisons until the dialogue box contains a list of three comparisons, numbered 1, 2 and 3. When we have done this, we click on OK. This procedure appears in Figure 9. The results of the output appear in Figure 10.

Reading across the output, we scan each line for the *t* value and the *p* value (Sig.). From this output we see that for the PI group there is a significant difference for each pairwise comparison. We would report it like this: “The results of the paired-samples *t* tests yielded a significant difference between the pretest and posttest 1, $t(21) = -12.304, p = .000$, a significant difference between posttest 1 and posttest 2, $t(21) = 2.592, p = .017$, and a significant difference between the pretest and posttest 2, $t(21) = -10.844, p = .000$. These results indicate that the PI group made a significant gain from pretest to posttest, dropped down somewhat from posttest 1 to posttest 2, but still had significant gains at posttest 2 compared to the pretest.”

We repeat the procedure above for our data set on just the Control group. The SPSS output yields the table in Figure 11. Again, reading across the lines we see that no comparison yielded any significant differences. We could report this information the following way: “As for the Control group, no pairwise comparison yielded any significant differences: pretest vs. posttest 1, $t(15) = -1.566, p = .138$; posttest 1 vs. posttest 2, $t(15) = 1.952, p = .070$; pretest vs. posttest 2, $t(15) = .565, p = .580$.”

Figure 10 SPSS results for *t* tests on interpretation test for PI group

What do our results show, then? The results of the repeated measures ANOVA along with the subsequent follow-up analyses show that the PI group made significant gains on the interpretation test while the Control group did not. What is more, although the PI group's scores declined from posttest 1 to posttest 2, the scores were still significantly higher at the end of the study than those on the pretest, suggesting at least a short-term (two-week) durability for the effects. To be sure, we have not answered our question regarding whether or not the effects of PI are transferable to tasks on which the participants were not trained (i.e., output-based tasks). If we had the space, we could present the analyses for both the sentence-level production test and the reconstruction test, repeating what we did for the interpretation test. And, if we had done this, we would show that the results are basically the same and that the effects do transfer to novel tasks unrelated to treatment type (see VanPatten & Uludag, 2011). We leave these analyses for readers to try on their own.

To be sure, repeated measures ANOVAs are not restricted to instructed SLA research in which treatment variables are manipulated; they are used anytime a researcher wants to compare groups of participants at one time and at a later time on the same measures (e.g., examining the effects of study abroad). Repeated measures can also be used to compare subcomponents or categories of items in a test when each participant has taken all parts of the test or performed with each item. For example, we can imagine a scenario in which participants took a test that included real regular verbs and real irregular verbs but also nonsense verbs that resembled both regular and irregular verbs (e.g., *swim*, *swam*, *drim*, *dram*). Assuming an equal number of each set of items and that what the participant did with each item was the same, the researcher could make use of a repeated measures ANOVA to see how participants performed on the various kinds of verbs. In short, repeated measures ANOVAs can be used when the measurement and number of items are the same, but groups of items can be treated as “separate” tests.

Cognitive Second Language Acquisition: Overview

JOHN WILLIAMS AND MARIANNE GULLBERG

Cognitive approaches to second language acquisition are characterized by an interest in how the human mind deals with language in learning; in what language learners know and how they use that knowledge in speaking and understanding. The aim is to understand how and under what conditions learners construct and organize knowledge, and how they then deploy that knowledge under the time-pressures of real language use in interaction and communication. Of key interest are the ways in which cognitive systems and abilities, partly conditioned by our biology, interact with external aspects of language and learning such as the properties of the language being learned, the context and situation, and so forth. Traditionally, these different views on language, acquisition, and learner-internal or learner-external factors have been examined in different theoretical and empirical domains. Despite their differences, all approaches share fundamental assumptions about the role and status of the NATIVE SPEAKER as a point of comparison and benchmark, although this notion has also received theoretical attention recently.

This section does not aim to give a historical overview of all concepts and approaches that have paved the way for the current state of the field, but rather to exemplify and illustrate some of the current key theoretical and empirical strands of investigation. In doing so, it brings together findings from many disciplines ranging from applied linguistics, linguistics, psycholinguistics, psychology, and cognitive neuroscience. The scholars representing these fields often publish in different parts of the literature, not necessarily under the heading of applied linguistics, and target different linguistic levels, phenomena, and factors separately. But the diverse perspectives and the scholars that represent them all contribute to our understanding of the multifaceted phenomenon that is cognitive second language acquisition.

The Input

Input plays a crucial role in cognitive approaches to SLA with the debates revolving around the extent to which properties of the input shape development. In such a perspective it becomes vital to examine those properties in detail and the effects of crosslinguistic diversity and typology (see *TYPOLOGY AND SECOND LANGUAGE ACQUISITION*) on acquisition, including potential modality effects such as in the *SECOND LANGUAGE ACQUISITION OF SIGN LANGUAGE* or crosslinguistic differences in reading, scripts, and orthographies (see *SECOND LANGUAGE READING, SCRIPTS, AND ORTHOGRAPHIES*). In a similar vein, the consequences of acquiring a new language in the presence of several others is examined in studies of *THIRD LANGUAGE ACQUISITION*, where not only properties of the languages, but also factors such as recency of use and proficiency levels in the languages involved are examined.

Cognitive Approaches to Acquisition

Cognitive approaches to acquisition reflect the polarization between nativist and empiricist philosophies. The nativist view is that the child is born with an innate universal grammar that is represented according to the principles of modularity in an encapsulated language faculty that is separate from other cognitive abilities. This inspires a particular approach to input processing (see *INPUT PROCESSING IN SECOND LANGUAGE ACQUISITION*) that stresses the role of innate knowledge of relevant linguistic categories, allowing the child to induce the structure of the language(s) to which it is exposed despite the assumed “poverty” of the input. The main issues in this field are whether universal grammar (UG) is accessible in SLA, and whether native-like proficiency is attainable by adult learners (see *UNIVERSAL GRAMMAR AND SECOND LANGUAGE ACQUISITION*, *MODULARITY IN SECOND LANGUAGE ACQUISITION*, *CRITICAL PERIOD*, *FOSSILIZATION*). At the other extreme, the empiricist approaches, latterly referred to as *EMERGENTISM*, assume no innate knowledge, emphasize the richness of the input as the sole basis for learning, and focus on the functions of linguistic forms, as illustrated by the *COGNITIVE LINGUISTICS OF SECOND LANGUAGE ACQUISITION*. They appeal to general cognitive learning mechanisms that are not specific to language, specifically principles of associative learning as exemplified in the *COMPETITION MODEL* and *CONNECTIONISM*. Between these positions we find research that considers the interplay of UG and properties of the input and general cognitive principles and their effects on all learners, leading to the study of *LEARNER VARIETIES*, examined as languages in their own right.

Representations and Processing

Research on second language representation and processing builds on the models of processing developed in the context of monolinguals and explore the implications of multilingualism. The essential question motivating this research is the extent to which second language (L2) representation and processing are separated from, integrated with, or parasitic upon the first language (L1), and the extent of crosslinguistic influence (see *CROSSLINGUISTIC INFLUENCE IN SECOND LANGUAGE ACQUISITION*), both uni- and bi-directional (from the L1 onto the L2, and vice versa). Research on *LEXICAL ACCESS IN BILINGUAL VISUAL WORD RECOGNITION*, *SPOKEN WORD RECOGNITION IN SECOND LANGUAGE ACQUISITION*, *SPOKEN WORD PRODUCTION IN SECOND LANGUAGE ACQUISITION*, and *ORGANIZATION OF THE SECOND LANGUAGE LEXICON*, all shows that even though a person is performing a task in a single language there are unconscious influences from their other languages. This suggests integration of the language systems, but also raises questions about *INHIBITION AND CONTROL IN SECOND LANGUAGE ACQUISITION* in determining which language a multilingual speaker uses. With regard to accessing the meanings of words, psychological *MODELS OF LEXICAL AND CONCEPTUAL REPRESENTATION IN SECOND LANGUAGE ACQUISITION* assume shared conceptual representations, but access via the L1 at early stages of acquisition (i.e., the L2 is parasitic on the L1) with direct L2 form–meaning mappings acquired with experience.

Research on *SENTENCE AND DISCOURSE PROCESSING IN SECOND LANGUAGE COMPREHENSION* suggests that the same processing principles apply in L1 and L2, and that there is similar crosslinguistic influence as for lexical processing. Of particular interest here is whether native-like processing can be acquired in areas of grammar that are different from the L1 but also the extent to which the same end result can be reached through different processing routes. Similar themes emerge in relation to *SENTENCE PRODUCTION IN A SECOND LANGUAGE* with the additional problem of selecting language-appropriate semantic content for expression in the correct morphosyntactic form to reflect one’s ideas, or *THINKING*

FOR SPEAKING IN SECOND LANGUAGE ACQUISITION, raising the issue of the acquirability of lexicalization patterns that are different from the L1. Turning this issue around, one can ask whether differences in means of expression across languages cause differences in general cognition outside of language, the issue of LINGUISTIC RELATIVITY AND SECOND LANGUAGE ACQUISITION, and whether learning an L2 changes the way you think.

All of the above research uses behavioral methods including crossmodal analyses involving gesture (see GESTURE ANALYSIS IN SECOND LANGUAGE ACQUISITION) and online psycholinguistic methods (see ONLINE PSYCHOLINGUISTIC METHODS IN SECOND LANGUAGE ACQUISITION RESEARCH) to examine moment-by-moment processing. Research on BRAIN ACTIVITY DURING SECOND LANGUAGE PROCESSING (ERP) and also SECOND LANGUAGE REPRESENTATION IN THE BRAIN provides converging evidence, showing similar brain responses in L1 and L2 and similar localization of brain activation for different language processes. Thus there is very strong support for integration of L1 and L2 knowledge and processing.

Learning Mechanisms and Educational Consequences

With regard to specific learning mechanisms, the cognitive approach appeals to general principles of memory and learning from psychology. These are relevant to an overall theory of SLA regardless of whether one is a nativist or an empiricist because even nativists have to admit that not all of language is UG-constrained, and certain aspects have to be learned using general cognitive mechanisms. The debate here centers on the extent to which people can spontaneously pick up different aspects of language from input even though their task does not require them to do so (see INCIDENTAL LEARNING IN SECOND LANGUAGE ACQUISITION), or without even being aware of what they have learned (see IMPLICIT LEARNING IN SECOND LANGUAGE ACQUISITION), or whether they can only learn by being taught or consciously working out rules for themselves (see EXPLICIT LEARNING IN SECOND LANGUAGE ACQUISITION). Central to these debates are the roles of attention, noticing, and awareness in learning (see ATTENTION, NOTICING, AND AWARENESS IN SECOND LANGUAGE ACQUISITION). Most of this research concerns the acquisition of knowledge, but with regard to the acquisition of fluency in performance processes of AUTOMATIZATION, SKILL ACQUISITION, AND PRACTICE IN SECOND LANGUAGE ACQUISITION are critical.

The study of the cognitive processes underlying SLA has consequences for pedagogy. TASK-BASED LEARNING: COGNITIVE UNDERPINNINGS focuses on how the design characteristics of tasks affect the cognitive mechanisms underlying language learning. More specifically, the INTERACTION APPROACH IN SECOND LANGUAGE ACQUISITION explores how learner–teacher conversation provides opportunities for learning through switches of attention from meaning to form. Emergentist approaches stress the role of the lexicon and the emergence of grammar from formulaic language, hence an understanding of the cognitive processes underlying VOCABULARY ACQUISITION IN SECOND LANGUAGE ACQUISITION, and learning FORMULAIC LANGUAGE AND COLLOCATION becomes critical to devising optimal methods of instruction. Emergentism also stresses the functions of language forms, and cognitive linguistics can play a role in suggesting how these can be made transparent to the learner. Research on COGNITIVE APPROACHES TO COMMUNICATION STRATEGIES focuses on both interactive and psycholinguistic aspects of learners' language use with potential consequences for both instruction and learning. Working from the perspective of models of language processing PROCESSABILITY THEORY AND TEACHABILITY predicts the natural course of development and L1 influences during SLA with consequences for the staging of explicit instruction. The study of FOSSILIZATION can help target explicit instruction on just those grammatical features that are predicted to be problematic for the learner.

Individual Differences

Individual differences in second language learning success can be related to differences in underlying cognitive abilities, and understanding these relationships can shed light on the cognitive mechanisms of SLA. The age of the learner may impact upon the learning process. For example, ultimate native-like attainment might only be possible if acquisition begins during a CRITICAL PERIOD. More generally, the notion of APTITUDE IN SECOND LANGUAGE ACQUISITION may be decomposed into different cognitive abilities all of which show variability between individuals. Recently attention has focused on working memory, and its further division into phonological short-term memory (see WORKING MEMORY IN SECOND LANGUAGE ACQUISITION: PHONOLOGICAL SHORT-TERM), which is especially implicated in vocabulary learning, and an attentional component, which is implicated in explicit learning (see WORKING MEMORY IN SECOND LANGUAGE ACQUISITION). From a different perspective, research on PERSONALITY IN SECOND LANGUAGE ACQUISITION has investigated whether language-learning success tends to be associated with certain personality traits.

Biographies

Many distinguished scholars have contributed to the development of cognitive approaches to second language acquisition. Many key figures are represented in other areas of this encyclopedia, but the following scholars feature in biographical entries here: Ellen BIALYSTOK, Vivian COOK, Robert DEKEYSER, Nick ELLIS, Rod ELLIS, Jan H. HULSTIJN, Judith KROLL, Michael H. LONG, Terence ODLIN, Peter ROBINSON, Jacquelyn SCHACHTER, Richard SCHMIDT, and Peter SKEHAN. They represent different disciplines and research traditions but their common and long-standing focus on the nature and processes of SLA has provided the field with some of its most influential models, theories, and tools.

Cohen, Andrew D.

NORIKO ISHIHARA

Being a prolific researcher and an exceptionally extroverted individual, Andrew D. Cohen (born March 14, 1944) is known as a researcher in applied linguistics, teacher and educator in second/foreign language learning and teaching, learner of 11 languages (Aymara, Quechua, German, Italian, and Latin, with working knowledge of Spanish, French, Hebrew, Portuguese, and some Japanese and Arabic), vigorous international traveler and lecturer, timely and informative e-mail responder, energetic squash player (until age 66), cyclist in all weather, enthusiastic trumpeter and guitarist, and father of two children with one grandchild as of 2010. His work encompasses several subfields of applied linguistics, including assessment, bi/multilingualism and immersion education, language learner styles and strategies, pragmatics, and research methodology.

Perhaps Cohen's most influential contribution to applied linguistics is his strategic approach to language learning and teaching. Cohen's work in developing a program for styles- and strategies-based instruction (SSBI) reflects his beliefs in independent language learning, in which learners are trained to self-motivate and self-regulate their studies. His work includes a research study validating the effectiveness of integrating language learning and use strategies into language instruction, a teachers' guide to SSBI (Cohen & Weaver, 2006), and an annual summer institute on the topic at the Center for Advanced Research on Language Acquisition (CARLA) housed at the University of Minnesota until 2009. In collaboration with others including Michael Paige and Barbara Kappler, Cohen has written guides for learners, instructors, and program professionals on how to maximize students' learning of language and culture through the use of strategies while studying abroad (Paige, Cohen, Kappler, Chi, & Lassegard, 2006; Kappler Mikk, Cohen, & Paige, 2009), and conducted research with students in French and Spanish-speaking countries.

In the area of cross-cultural/interlanguage pragmatics, Cohen's research with Elite Olshtain in the early 1980s on the speech act of apologies is known as one of the first seminal attempts to empirically investigate speech act realization, elucidating the major components of apology-specific strategies. More recently, as part of his CARLA projects, Cohen combined his strategic approach with the development of pragmatic competence. In this effort, he directed the development of Web-based curricular materials on second-language Japanese and Spanish pragmatics and collaboratively studied the effects of those strategies-based materials on the development of learners' pragmatic competence. Cohen was also involved in creating and co-instructing at a summer institute on learning and teaching pragmatics at CARLA (from 2006), and co-authored a teachers' guide on this topic (Ishihara & Cohen, 2010).

Cohen's work in bi/multilingualism, bi/multilingual education, and immersion education dates back to the early 1970s at the beginning of his career. His doctoral dissertation (Cohen, 1972) was later published as a book entitled *A Sociolinguistic Approach to Bilingual Education: Experiments in the American Southwest* (Cohen, 1975). More recently, he conducted studies involving Spanish immersion education at the Adams School in St. Paul, Minnesota, and research at the Concordia Language villages with their German, French, Russian, and Norwegian summer immersion programs.

Cohen's research in the areas of second language assessment (e.g., Cohen, 1994) and research methodology often capitalizes on his expertise in other areas, particularly in SSBI

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

DOI: 10.1002/9781405198431.wbeal0152

and pragmatics. His investigations range widely, including research on test-taking strategies, assessment of speech act performance in the second language, oral language assessment, the use of summary tasks and written reformulations, the utility of verbal report in providing writing feedback and in researching pragmatic development, and the role of language learner strategies and strategy instruction in language teaching methodology. He also writes more generally about second language learning, teaching, theory, and pedagogy.

Cohen is a member of the Program in Second Language Studies at the University of Minnesota (until 2014). He served as the Director of the Language Resource Center at CARLA from 1993 to 2004 and has been active with numerous projects within CARLA as mentioned above. His most recent project with CARLA centered on the development of a Spanish grammar strategies Web site for learners, launched in the summer of 2009, which is intended to provide a model for teachers and researchers of any language on how to pass on successful learners' strategies in a given skill area (in this case, grammar) to other learners of that language.

Cohen was born in Washington, DC, and grew up there as well as in Long Island, New York. He holds a BA in French history and literature from Harvard University (1965) and an MA in linguistics from Stanford University (1971). In 1973, he received his PhD in international development education from Stanford University. Upon the completion of his BA, Cohen served as a Peace Corps volunteer in rural community development in the High Plains in Bolivia (1965–7), while he learned Aymara which was his third foreign language at the time. Later he was assistant professor in the English as a Second Language Section in the Department of English at the University of California at Los Angeles (1972–5). Cohen spent 16 years in Israel, where he served as a senior lecturer at the Centre for Applied Linguistics in the Faculty of Humanities at the Hebrew University of Jerusalem (1975–9) and then as associate professor of applied linguistics in the School of Education at the Hebrew University (1979–91). Since 1991, he has been teaching in the Program in Second Language Studies in the College of Liberal Arts at the University of Minnesota in Minneapolis (associate professor, 1991–3; full professor, 1993–present), where he is now in phased retirement and teaching only Fall semesters until the Fall of 2013.

The significant contributions that Cohen has made to the field of applied linguistics have been recognized in the form of the honors he has been awarded. He was designated Scholar of the College in the College of Liberal Arts at the University of Minnesota for 2002–5. He was also selected as the recipient of the 2006 Distinguished Scholarship and Service Award from the American Association for Applied Linguistics.

Collaborative Language Learning

NEOMY STORCH

The term *collaborate* means to share labor (co-labor) and hence collaborative language learning is often taken to mean assigning students to work in pairs (or small groups) on language tasks. The use of pair work in second language (L2) classrooms has grown in recent years. Pair work is deemed to provide learners with more opportunities to use the target language and thus accords with communicative approaches to language instruction. Pair work is also supported by most of the current theories informing second language acquisition research. For example, in Long's (1996) interaction hypothesis, interaction is seen as the means of making L2 input more comprehensible and thus facilitating L2 learning. In Vygotsky's (1978) sociocultural theory, the development of all higher order cognitive skills (including language learning) is said to emerge in social interaction (Lantolf & Thorne, 2006).

However, despite the widespread use and support for pair work in L2 classes, as students and teachers we have all probably experienced and observed pairs who do not seem to work well. Indeed one of the underlying assumptions in assigning students to work in pairs is that learners will collaborate rather than function merely as two individuals working autonomously in close proximity. Another related assumption is that the nature of the relationship that pairs form has no influence on language learning outcomes. Recent research findings suggest that not all pairs collaborate and that it is collaborative pair work that is conducive to language learning.

One of the first studies to consider the relational aspects of learner interaction was by Donato (1994). In his investigation of the relationships foreign-language learners formed when working in small groups, Donato distinguished between what he termed "collective groups" and "loosely knit groups." Some of the defining characteristics of collective groups included frequent requests for mutual assistance, which Donato termed "collective scaffolding," and a cohesive discourse pattern that was often indistinguishable from that of an individual speaker.

Building on Donato's work, Storch (2002, 2009) observed and recorded the talk of the same pairs of tertiary English as a second language (ESL) learners working on different tasks over a semester. Based on her data, Storch established a model of dyadic interactions with two intersecting continua (see Figure 1). The horizontal continuum reflects the learners' level of contribution and control over the task and ranges from low to high equality. The vertical continuum reflects the learners' level of engagement with each other's contribution and is thus termed *mutuality*. High mutuality describes interactions that are rich in reciprocal feedback and a sharing of ideas. At the other end, low mutuality reflects lack of engagement with each other's suggestions. The two intersecting continua form four quadrants, representing four distinct patterns of pair relations.

Pairs who display a collaborative orientation reside in the top half of the model, in quadrants 1 and 4. In quadrant 1, the pattern of interaction is truly collaborative: both equality and mutuality are relatively high. That is, both members of the pair contribute to the task and engage with each other's suggestion. The kind of assistance offered is bidirectional, with both learners offering assistance to each other or pooling their linguistic resources (collective scaffolding) to reach resolutions. In quadrant 4, the pattern is labeled

2 COLLABORATIVE LANGUAGE LEARNING

Figure 1 A model of dyadic interaction © Neomy Storch

expert/novice and reflects a tutor/tutee relationship. In such pairs, one learner takes a leading role but at the same time provides the kind of support and encouragement usually provided by the teacher.

The lower half of the model represents noncollaborative patterns of interaction. Quadrant 2 represents a pattern of interaction where there may be moderate to high equality, but a relatively low level of mutuality. In such pairs, both members of the pair contribute to the task but do not engage with each other's suggestion. This may occur either because the learners wrestle for control of the task or are unwilling to engage with each other's suggestion (a relationship labeled "dominant/dominant" in Storch, 2002, 2009), or both of these, or instances where the pair cooperate rather than collaborate. That is, the learners simply divide the task between themselves, with each participant focusing only on their part of the task.

Quadrant 3 represents a dominant/passive pattern. The dominant participant in such dyads takes control of the task and completes the task as if on his or her own. The other participant adopts a more passive, subservient role. There is little interaction in such patterns because there are few contributions, questions, or challenges forthcoming from the more passive participant.

Excerpt 1 comes from the data of Storch (2002, 2009) and is an example of the type of interaction found in collaborative pairs. The two participants contribute jointly to the task and engage constructively with their own and each other's suggestions. They engage in what Swain (2006) refers to as "linguaging": using language to make meaning and to deliberate about the language used. In Excerpt 1, we see evidence of learners using language to co-construct ideas by building and elaborating on each other's utterances (e.g., turns 2–9) and by seeking and providing mutual assistance (e.g., turns 19–20). Once ideas are formulated the learners engage with the utterances produced. There is corrective feedback in the form of explicit peer repair (e.g., turn 15) or recasting (e.g., turn 6) as well as positive feedback in the form of confirmations (e.g., turns 9, 10). There is also evidence of pooling resources, or collective scaffolding (Donato, 1994). In turn 16, the pauses suggest

that Mai may be searching for an appropriate verb. Charley suggests a verb (show) but then Mai notes a problem with subject verb agreement and Charley provides the appropriate correction.

- 7 Charley: English language fluency
- 8 Mai: English language fluency between two countries yeah? Vietnam and Laos
- 9 Charley: Yes and compare before they came here and now
- 10 Mai: Yes
- 11 Charley: You can separate it here
- 12 Mai: Yeah . . . first we . . . mm the
- 13 Charley: Perhaps you should write
- 14 Mai: Yeah I write yeah from the information of the chart yeah . . . [writing]
information of the chart
- 15 Charley: No from figure 3
- 16 Mai: Ah figure . . . figure 3? From figure 3 . . . figure 3 ah
- 17 Charley: Show the information
- 18 Mai: Show the information . . . it it's
- 19 Charley: Yeah it's ok it shows . . . the data or the percentage?
- 20 Mai: Should be the percentage

It is important to note that collaboration is different from cooperation. Excerpt 2 comes from the data collected by Tan who compared the nature of pair work in face to face and via computer mediated interaction in a class of adult learners of Chinese as a L2 (see Tan, Wigglesworth, & Storch, 2010). As can be observed in Excerpt 2, although both Jan and Ben contribute to the task (a short composition), there is little engagement in each other's suggestions and very little evidence of feedback or of a pooling of resources. That is, there is no evidence of languaging or the type of cohesive, collaborative dialogue evident in Excerpt 1.

{At 12 start class to study English}
- 10 Ben: *jiudianban ta qu Moerben daxue*
{At 9:30 he goes to Melbourne University}
- 11 Jan: *hao*
{Good}
- 12 Ben: *hao yidian zai fandian chi wufan*
{Good. At one o'clock at restaurant eat lunch}

These different patterns of dyadic interaction have since been reported in a number of studies in different contexts. For example, Ives (2004) found evidence of collaborative, expert/novice, and expert/passive patterns of interaction in a primary L2 class where grade 6 learners were paired with native-English-speaking children. Aldosari (2008), in a study conducted in an English as a foreign language (EFL) class (Saudi Arabia) where learners were paired according to their L2 proficiency, found more evidence of collaboration in pairs of equal proficiency (high-high and low-low) than in pairs where learners had different proficiency (high-low). Kim and McDonough (2008), in a study conducted in South Korea with learners of Korean as a second language, also reported different patterns of pair interaction depending on whether the learner worked with an interlocutor of the same or with a higher L2 proficiency level. However, L2 proficiency level may not be the sole reason explaining why learners form different patterns of interaction. Storch (2004) suggested that collaboration can best be explained by reference to individuals' goals and attitudes to the activity of pair work. These goals and attitudes are in turn shaped by an individual's history of language learning and by cultural backgrounds. Collaboration is most likely to occur when both members of the pair share goals and view the activity and the contribution of each member as valuable.

Given that learners are likely to form different patterns of interaction when assigned to work in pairs, the important question to consider is whether these patterns have implications for language learning. As Excerpt 1 shows, collaborative dialogue is rich in language learning opportunities. That is, when learners collaborate they deliberate about language use: they provide suggestions, countersuggestions, explanations, and feedback to each other. A number of studies (e.g., Storch, 2002, 2009; Watanabe & Swain, 2007; Kim & McDonough, 2008; Tan et al., 2010) have reported more evidence of deliberations about language in the data of pairs who collaborated than in noncollaborative pairs. Thus these studies suggest that collaborative pair work provides greater potential for language learning than non-collaborative pair work.

A small number of studies have also shown direct links between the nature of dyadic interaction and language learning outcomes. Storch (2002, 2009) traced for the presence of linguistic items over which the learners deliberated in the pair talk appearing in the learners' subsequent individual production. She found such evidence in the data of the collaborative pair and in the expert/novice pair more so than in the noncollaborative pairs. Watanabe and Swain (2007), using a pre-/posttest design, found greater evidence of learning in the data of pairs who collaborated than in those who exhibited a noncollaborative orientation.

The nature of interaction has been found to have an impact not only on language learning outcomes but also on test performance outcomes. For example, Galazi (2008), who studied the interactional patterns of pairs of candidates in the First Certificate in English test, reported that pairs who exhibited a collaborative orientation achieved higher scores than those who interacted in a cooperative pattern.

In language classrooms, which are essentially social events (Block, 1996), interactions between participants may have multiple meanings and in turn different language learning outcomes. As a growing number of studies have shown, not all pair work qualifies as

collaborative, and some dyadic patterns may be counterproductive. A greater awareness and understanding of the nature of collaboration is therefore important in order to enhance the learning opportunities pair work offers language learners.

Colonialism and Language Policy and Planning

ROBERT PHILLIPSON

Key factors that account for European languages and Christianity being transplanted worldwide are identified. The privileged position of excolonial languages has been consolidated through Western influence on educational policies and linguistic imperialism. The existence of alternative language policies that create greater social justice shows that much-needed change is possible.

European languages have accompanied political and economic influence, invariably backed up by military might. The present-day strength of English, French, Spanish, and Portuguese in the Americas, Africa, Asia, Australasia, and the Pacific is a direct consequence of successive waves of colonization. The dominance of English, rather than French, in North America and India is due to British military successes. The external colonization of English built on internal suppression of all the Celtic languages of the British Isles (Welsh, Gaelic, etc.).

The significance of language for political control was appreciated from its inception. In 1492 Queen Isabella of Spain was presented with a plan for establishing Castilian as “a tool for conquest abroad and a weapon to suppress untutored speech at home” (quoted in Illich, 1981, p. 35). For its author, Nebrija, the first modern grammarian and language planner, “Language has always been the consort of empire, and forever shall remain its mate” (p. 34). The language was to be fashioned as a standard in the domestic education system, as a means of social control, and harnessed to the colonial mission elsewhere.

Christianity accompanied European languages worldwide, just as Arabic has been integral to the spread of Islam. In central and southern America, the colonizers encountered well-established local languages of empire, and there was a protracted debate between missionaries seeking to preach the gospel using these languages, as opposed to those who favored Spanish (Heath, 1972). An official British survey of sub-Saharan Africa in 1938 noted that “until very recently ‘nine-tenths of the education in Africa was in the hands of missionary bodies’. The same was largely true for most other parts of the tropical Empire and for indigenous people trapped within white settler societies” (Etherington, 2005, p. 11). Missions were part of “a larger drama—the spread of modernization, globalization, and Western cultural hegemony” (p. 4), with missionaries often preceding colonial armies and administrators.

Missionaries devised orthographies for initial literacy work and evangelization in many African languages. There is considerable debate about whether they “created” African languages invalidly (Makoni & Makoni, 2009). There is also serious concern about how missionaries in the 21st century are integrating their Christianization goals with English teaching, often covertly (Wong & Canagarajah, 2009). The Wycliffe Bible Translators, the partner organization of the Summer Institute of Linguistics, has the goal of making “the Bible accessible to all people in the language they understand best. To make this vision reality, Wycliffe also focuses on literacy development, community development and church partnerships” (Wycliffe, *n.d.*). Missionary goals worldwide are promoted through processes that are marketed as culture-free general education, whether a minority language

2 COLONIALISM AND LANGUAGE POLICY AND PLANNING

or English is used. While it is true that Christianity has been appropriated for local purposes by colonized peoples, missionaries are integral to global dominance by the USA and its acolytes.

The colonizers of North America and India felt they had a divine right to promote their beliefs and language. By the mid-19th century English was being projected as

a strong, a harmonious, a noble language . . . Before another century has gone by it will, at the present rate of increase, be spoken by hundreds of millions . . . That language is rapidly becoming the great medium of civilization, the language of law and literature to the Hindoo, of commerce to the African, of religion to the scattered islands of the Pacific. (Edwin Guest, 1838, quoted in Crowley, 1989, pp. 71–2)

In territories where Europeans settled, indigenous peoples experienced physical genocide, and survivors were subjected to Westernized education policies and linguicide: “we have room for but one language here, and that is the English language” (US President Theodore Roosevelt, 1919).

In the British Empire there was a recurrent debate about the merits of using English or the languages of colonized peoples in their education (Rahman, 1999). English literature was developed as a school subject in India, where it proved its worth as an instrument of social control, before being introduced in British schools (Viswanathan, 1989). British literature still dominates the curriculum of departments of English in postcolonial universities, building on the rationale that it is the ultimate humane education (see Phillipson, 2009, pp. 114–18, 138–9). In like fashion, in US colonies such as the Philippines, there was an insistence on an exclusive use of English in education from 1898 to 1940, and Filipinos had “the literary taste of an American” imposed on them, with lasting consequences (Martin, 2002). Russian was an instrument of ideological control in the Soviet Empire from Stalin’s time onward, with concepts such as bilingualism and international language signifying the replacement of other languages by Russian (Rannut, 1994).

Examinations in British colonies followed the UK system, which has been retained in many former colonies. *Examining the World: A History of the University of Cambridge Local Examinations Syndicate* (Raban, 2008) triumphantly documents how the content and language of school education are still determined in Cambridge, in liaison with local education authorities in Brunei, Mauritius, Singapore, and elsewhere. The growth of English-medium “international” schools for elites worldwide has consolidated this influence and created a new market for this educational business. It strengthens the position of English and British influence worldwide.

Linguistic and Educational Imperialism

There are similarities between taking Christianity worldwide and the secular gospel of “global” English. The transplantation and export of languages is sometimes referred to as language spread, which is shorthand for a host of variables that can account for the expansion of a language. The term is misleading, however, since it can be interpreted as signifying an agentless process, as though languages, like living organisms, expand and contract according to nature’s laws. In fact languages, like the many species of flora and fauna that Europeans have spread worldwide (involving ecological imperialism, Crosby, 1994), quintessentially involve human intervention. It is specific groups of humans who have taken their languages with them in each context, and successfully imposed them. Colonial policies have involved linguistic imperialism (Phillipson, 1992; Mühlhäusler, 1996). Gilbert Ansre, the Ghanaian sociolinguist, describes this (1979, p. 12) as

[t]he phenomenon in which the minds and lives of the speakers of a language are dominated by another language to the point where they believe that they can and should use only that foreign language when it comes to transactions dealing with the more advanced aspects of life such as education, philosophy, literature, governments, the administration of justice, etc . . . Linguistic imperialism has a subtle way of warping the minds of even the most noble in a society and of preventing him from appreciating and realising the full potentialities of the indigenous languages.

Linguistic imperialism has these features:

- it is a form of *linguicism*, a favoring of one language over others in ways that parallel societal structuring through racism, sexism, and class: Linguicism serves to privilege users of the standard forms of the dominant language, those with convertible linguistic capital;
- it is *structural*: More material resources and infrastructure are accorded to the dominant language than to others;
- it is *ideological*: Beliefs, attitudes, and imagery glorify the dominant language, stigmatize others, and rationalize the linguistic hierarchy;
- the dominance is *hegemonic*, it is internalized and naturalized as being “normal”;
- linguistic imperialism interlocks with a *structure of imperialism* in culture, education, the media, communication, the economy, politics, and military activities;
- in essence it is about *exploitation*, injustice, inequality, and hierarchy that privileges those able to use the dominant language;
- this entails *unequal rights* for speakers of different languages;
- language use is often *subtractive*, proficiency in the imperial language and in learning it in education involving its consolidation at the expense of other languages;
- linguistic imperialism is invariably *contested and resisted*.

In Africa “Education to many people came to mean simply the ability to speak and write English” (Mazrui, 1968, p. 186). “English was the official vehicle and the magic formula to colonial elitedom” (Ngũgĩ wa Thiong’o, 1986, p. 12). Although many investigative reports on the British Empire stressed the need to strengthen local languages, policies of economic underdevelopment and linguistic underdevelopment functioned in parallel, and tied the peripheral economies and languages to global centers of power.

One of the most durable legacies of colonialism has been language:

Years after the attainment of political independence, the majority of African independent states have continued to practise linguistic policies inherited at the time of independence, where, on the whole, foreign colonial languages are more favoured than the languages indigenous to the African continent. (Organization for African Unity Inter-African Bureau of Languages 1985, p. 7)

The pedagogy of global English is based on five tenets (Phillipson, 1992): English is best taught monolingually; the ideal teacher of English is a native speaker; the earlier English is taught, the better the results; the more English is taught, the better the results; if other languages are used much, standards of English will drop. All five tenets are professional fallacies: the monolingual fallacy, the native-speaker fallacy, the early-start fallacy, the maximum-exposure fallacy, the subtractive fallacy. These fallacies are central to the billion-dollar “English-language teaching” business of the UK and USA: teacher training, the export of know-how, textbooks and reference works, and so on. The French similarly invest in promoting French internationally, as a means of maintaining political and economic

interests, but their pedagogy suffers from comparable weaknesses. The World Bank has perpetuated the false privileging of European languages in African education (Mazrui, 1997).

A Paradigm Change?

There are pressures to change this state of affairs. African heads of state have established an African Academy of Languages with a mandate to promote mother-tongue-based multilingual education, so as to ensure that a greater proportion of African children succeed in education. The Bamako International Forum on Multilingualism (January 19–21, 2009) approved a set of recommendations to African governments and to “aid” organizations that should facilitate a reversal of current educational paradigms (see www.acalan.org). Children who benefit from literacy and concept development in a local language are more likely to succeed in learning additional languages. Such policies are not “against” particular languages; they are intended to combat linguicist misuse of the languages. They reflect the fact that there is a consensus on how multilingual education can best be organized, and an awareness of the need for language policy and planning to be adjusted accordingly, as is now happening in many parts of the world (Skutnabb-Kangas, Phillipson, Mohanty, & Panda, 2009).

In the postcolonial world, a continuation of the asymmetrical relationship between North and South requires the complicity of local elites and a continuation of exploitative policies, including language policies. It also builds on the ethnocentricity and blindness to the nature of linguistic hierarchies and dominance that characterize books on ‘global’ English (reviewed in Phillipson, 2009). When Gordon Brown was due to make his first visit to India and China (January 17, 2008) as UK prime minister, he announced a plan to make British English “the world’s common language of *choice*” and to ensure that it is taught at primary level as a core skill. He omitted to mention that English learning is very big business for the UK. What “choice” means for schoolchildren in the south has been lucidly explained by the Tanzanian scholar Casmir Rubagumya (2004, pp. 134, 139):

European languages were *imposed* on Africa in the colonial period. African people as communities did not *choose* to learn those languages. . . . Individuals who do not go to school, and therefore do not learn European languages, do not choose not to go to school. They do not have access to schooling. . . . Giving false hopes that everybody can have access to “World English” is unethical.

Language policy and planning need to change so that the harmful consequences of the colonial linguistic inheritance are reduced.

Commercial Translation

GEOFFREY S. KOBY

Commercial translation is the translation of a source text (a written original) into a written target text, generally by a freelance professional translator, for a commercial purpose and for remuneration, often with short deadlines. The translation industry operates largely using an agency model: translation agencies work with clients to determine translation needs, then contract with freelance translators who produce the translation using a “translate–edit–proof” model where one translator produces a translation, a second translator in the same language pair (the “editor”) checks for accuracy and revises the translation, and a proofreader checks the target text for correctness. Translation agencies also provide other services to clients, such as desktop publishing. Some professional translators also provide the entire translation service to direct clients.

Commercially translated text types generally fall within two large domains: (a) business-related, legal, and financial translation; (b) scientific, technical, and medical translation. In these domains, the original document generally is characterized by a functional purpose which generally remains similar or identical in the translation, resulting in a translation approach in these texts that is normally communicative (as opposed to esthetic) and domesticating (i.e., making the translated text similar to original texts in the target culture for a similar or identical purpose). Advertising/marketing texts constitute a special challenge due to the combination of communicative and esthetic factors as well as the need to appeal to the reader. According to an American Translators Association (ATA) survey, commercial translators generally focus on one of the two broad domains listed above, with the greatest number specializing in business/finance (57%) and law (54%), or in medicine (46%) and industry and technology (39%), although many specialize in multiple areas (American Translators Association, 2007, p. 9). The majority of respondents to the survey worked as independent contractors, with 52% full time and 28% part time, while only 12% worked in-house in the private sector. Although it is difficult to determine the size of the translation market due to its fragmentation and freelance nature, the research firm Common Sense Advisory (www.common senseadvisory.com) reports that commercial translation industry volume is predicted to reach \$25 billion by 2013. The US Bureau of Labor Statistics (2010) reports, “Interpreters and translators held about 50,900 jobs in 2008. However, the actual number of interpreters and translators is probably significantly higher because many work in the occupation only sporadically,” while a recent European Commission report indicates an “assumed value of the translation and interpreting sector, comprising software localization and website globalisation activities, of 5.7 billion € in 2008” (2009, p. iv). The translation industry is “one of the most fragmented in the world . . . out of 700 participants [companies], 43% have no employees at all . . . and 36% have between 1 and 10 employees” (p. 23f.).

Literary translation is usually considered to be a separate area different from commercial translation due to differences in approach (esthetic and possibly foreignizing, i.e., highlighting differences instead of adapting to target-culture norms), deadlines (usually longer), and remuneration (usually less). Commercial interpreting (of an orally produced text, often in a legal, medical, or social services setting) is also considered to be a separate area, although some professional translators also interpret.

2 COMMERCIAL TRANSLATION

Companies needing translation services expect professional translators to be able to write as specialists in a particular field in order to create texts that professionals in such a field (e.g., accountants or physicians) would be able to use with the same facility as documents originally produced in their culture. Professional translators sometimes hold degrees in a professional field (e.g., law or engineering), but frequently acquire passive knowledge of a field through coursework and other reading. As Clark puts it, “there is simply no such thing as, say, a Master’s Degree in Translation of Hungarian Car Repair Manuals into English from Semilegible PDFs” (2010, p. 10). Thus, for instance, a business/financial translator is capable of researching and understanding (and reproducing) business plans, annual reports and other financial reports, minutes of business meetings, prospectuses for stock offerings, and so forth. This domain also impinges on the legal area due to the need to understand and translate excerpts from accounting and financial legislation. The legal area also covers translation of contracts, legal briefs, lawsuits, and court rulings, and so on. Patents, although containing formulaic legal language, are often not considered legal translation since most of the content is generally technical. Thus scientific/technical translators translate patents, as well as technical reports, specifications, engineering documents, manuals for equipment, software and hardware, scholarly and professional articles on scientific topics, and so forth. This domain also includes the translation of product inserts and packaging materials for consumer products. Some such translators also focus on localization of products, manuals, and software interfaces for foreign cultures; in these cases, a single source text is sometimes translated into multiple target languages for use in multiple world markets. Medical translators specialize in the biological, chemical, and professional jargon and language necessary to make their work comprehensible in the medical world. A specialized area of medical translation is medical surveys, which are validated in the source language, translated, back-translated, and revalidated to ensure that medical survey research in multiple languages is valid.

Some texts can be categorized into multiple specialty areas, such as a business plan or prospectus for a company specializing in medical technology, for example. Such a text may include description of the company’s physical plant, a narrative of the company’s history, specialized financial analyses, and specialized descriptions of the medical technology. In such a case, the translation may be divided among multiple specialized translators to ensure high quality.

In addition to subject matter specialization, commercial translators must have a variety of skills and carry out a variety of specialized activities. Translators normally receive assignments in electronic form via e-mail, meaning that they must handle e-mail attachments and keep track of many files, following agency-specified file-naming conventions. Fundamentally, all commercial translators carry out the core function of translation, typically while consulting a variety of reference works, particularly specialized bilingual dictionaries in the domain, bilingual Internet glossaries, parallel texts, and corporate Web sites. For the most part, they create their translation using one of several mainstream software tools such as the Microsoft Office suite, or other specialized text or graphics management programs. Frequently, translators are also requested to copy the formatting of the source text, at least roughly, which requires additional skills. Many translators also use what is called a Translation Environment Tool or TEnT, which is specialized computer-aided translation software designed to support professional translators by managing specialized terminology and storing the translator’s sentences in a translation memory tool for future reuse. Some translators also use other specialized tools to localize software for a specific locale. Machine translation (MT; automatic translation by computer without human intervention), on the other hand, was until recently rarely used by professional freelance translators. A small number of professional translators working in large companies do prepare texts for input into MT software (pre-editing), or revise the software’s output to make it acceptable for

human use (post-editing). The quality of MT has made a leap forward with the advent of statistically based MT applications, notably Google Translate (<http://translate.google.com>), and is therefore increasingly being integrated into TEnTs and working processes of some freelance translators in order to increase productivity.

It is often necessary for translators/translation agencies to educate their clients due to popular misconceptions about the nature, complexity, and cost of translation. Frequent misconceptions include the idea that any bilingual speaker is capable of translating, that anyone who has studied a foreign language is competent to translate, that students or academics are capable of professional translation, and that anyone armed with the appropriate dictionaries will produce an accurate and adequate translation. The American Translators Association has made two publications available on its Web site to assist professionals in combating this notion: Durban's *Translation: Getting It Right* (2003), and Durban and Melby's *Translation: Buying a Non-Commodity* (2008).

As noted above, advertising/marketing texts require a special translation approach. Following review of the source text, the translator may recommend that the client contract with an advertising agency in the target culture. However, some companies prefer to have a unified message across multiple cultures (e.g., the McDonald's corporate slogan "I'm lovin' it"/"ich liebe es"/"c'est tout ce que j'aime"), requiring a translator/team to adapt the source language message to the target language culture, while complying with corporate design guidelines. Such messages must be carefully planned to avoid misunderstandings or giving offense due to culturally or linguistically bound messages such as wordplays or specific images. This thorny problem was the topic of an entire special issue of *The Translator* in 2004 (Adab & Valdés, 2004).

In the USA, professional translators generally charge by the word (particularly for translation) or per hour (editing and formatting). In Europe, charges are often by line (a specified number of characters, often 55). Since most translators are freelance professionals running their own businesses, rates are negotiated between the agency/direct client and the translator. One point of contention is whether to charge by source text word count or target text word count.

Professional associations play a large role in the translation industry. The International Federation of Translators (FIT; www.fit-ift.org), an umbrella organization whose membership is more than 100 national translation associations, offers a triennial world congress, advocates for training, working conditions, and recognition of the profession, and publishes a journal and a newsletter. In the USA, the 11,000-member American Translators Association (ATA; www.atanet.org) is the major professional association. Its membership includes professional translators and translation agencies, and its activities include a major annual conference, regional and special-topic conferences, local chapters, scholarly publications, a member magazine, and a certification program. Similar programs exist in other countries. For instance, Canadian translator organizations operate at the provincial level, while in England the primary association is the Institute of Translation and Interpreting (ITI; www.iti.org.uk), and in Australia, the Australian Institute of Interpreters and Translators (AUSIT; www.ausit.org). Similar associations exist in other countries throughout the world. Other professional associations exist specifically for interpreters or literary translators. (See www.lexicool.com/translator_associations.asp for a list of translator and interpreter associations.)

One of the major issues for professional translators is the question of who is qualified to be a professional translator. In some countries, the term "translator" or its equivalent is a protected professional title, and only those who pass a government examination are "certified," "accredited," "authorized," or "sworn" translators or some similar title. In the USA, the status of translator is not protected, but professional certification is available through the American Translators Association, which started its professional certification

program in 1973. It currently includes more than 24 language combinations and more than 2,000 certified translators, despite a pass rate of less than 20% (Stejskal, 2003b, p. 13). Other credentialing options in the USA include federal government examinations for court interpreters (Stejskal, 2003a, p. 13), a credential for judiciary translators and interpreters in Spanish developed by the National Association of Judiciary Interpreters and Translators (NAJIT; www.najit.org/). According to the ATA survey, the majority of respondents (63.9%) are not certified translators (ATA, 2007, p. 6). In Australia, the National Accreditation Authority for Translators and Interpreters (NAATI; www.naati.com.au), a government-owned corporation, provides accreditation testing on a variety of levels (paraprofessional, professional, and advanced translator and interpreter). In the United Kingdom and Ireland, on the other hand, translators are not certified; instead, translators certify their translations as a member of a professional organization (Stejskal, 2002, p. 12).

According to the ATA survey, the majority of commercial translators (61%) were not born in the USA (ATA, 2007, p. 5). Thus they often will have been trained in institutions in their home countries. The training of these survey respondents varies widely, but most (88%) hold at least a bachelor's degree and more than half (55%) hold either an MA or a PhD (ATA, 2007, p. 8). However, one cannot assume that this training was in translation and interpreting studies; instead, many translators hold either a subject-matter degree or a general degree in a foreign language and culture (which may be English). Increasingly, however, the translation industry is becoming professionalized, and translation studies is becoming a recognized academic discipline with its own organizations and curricula offering professional training and professional degrees for prospective translators.

Common European Framework of Reference

ARI HUHTA

This entry focuses on the *Common European Framework of Reference for Languages: Learning, Teaching, Assessment* (CEFR), which, in the words of a non-European observer, is “one of the most ambitious examples of the gradual formation, shaping and . . . implementation of language education policies” (Byrnes, 2007, p. 641). The CEFR was designed by the Council of Europe (CoE), a pan-European organization that promotes human rights, mutual understanding, parliamentary democracy, and the rule of law. It advocates linguistic rights and language learning as a way of enhancing mutual understanding, and plurilingualism—an individual’s ability to use more than one language—is a key concept in CoE language policy (see CoE, 2008).

The roots of the Common Framework go back to the 1970s to definitions of notions and functions needed for communication (e.g., the Threshold Level by van Ek, 1977). Concrete development of the CEFR started in the early 1990s, and the final version of the Framework was published in English and French in 2001 (see North, 2000; Little, 2006, 2007, for details). The Framework has been translated into dozens of languages: currently, 33 language versions exist, including such non-European languages as Arabic, Chinese, and Japanese. For an updated list of language versions, go to www.coe.int/lang.

According to the Framework (CoE, 2001, p. 1), it provides:

a common basis for the elaboration of language syllabuses, curriculum guidelines, examinations, textbooks, etc. across Europe. It describes in a comprehensive way what language learners have to learn to do in order to use a language for communication and what knowledge and skills they have to develop so as to be able to act effectively.

By doing the above, the CEFR improves the transparency of language education, which will also “facilitate the mutual recognition of qualifications gained in different learning contexts, and accordingly will aid European mobility” (CoE, 2001, p. 1).

The view of language in the CEFR is action-oriented and considers “users and learners of a language primarily as ‘social agents’, i.e. members of society who have tasks (not exclusively language-related) to accomplish in a given set of circumstances, in a specific environment and within a particular field of action” (CoE, 2001, p. 9). Although the CEFR does not recommend particular teaching or testing methods, the action-oriented view strongly suggests that communicative, task-based approaches are particularly compatible with the CEFR (Little, 2006, p. 169). The CEFR sees language learning as a lifelong process that is not limited to school and that also includes informal learning.

In line with the CoE’s policies, the CEFR promotes plurilingualism and intercultural communication, which are aims shared by the European Union, the most important European political and economic organization. This has obvious implications for language curricula in Europe. The CEFR also introduces the idea that learners need not all learn in the same way, nor exactly the same things. It is, furthermore, entirely natural for learners to acquire “partial competences”—for example, an ability to understand a language without being able to speak it equally well.

The Encyclopedia of Applied Linguistics, Edited by Carol A. Chapelle.

DOI: 10.1002/9781405198431.wbeal0157

The CEFR includes two descriptive dimensions, horizontal and vertical. The vertical dimension is the best known and most widely used part. It is a proficiency scale comprising six successive levels: A1, A2, B1, B2, C1, and C2. Levels A2, B1, and B2 can be split into two sublevels thus increasing the total number of levels to nine (see North, 2000, 2007, on the origins of the CEFR scales). There are global scales for written and spoken reception (i.e., reading and listening), and for written and spoken production and interaction. Fifty-four specific scales were developed to describe different communicative activities, strategies, and learner competences within the above six main categories.

Central to the CEFR are “can do” statements: descriptors defining specific instances and contexts of language use. They are the building blocks of the scales but they also link the scales to many content categories of the CEFR. These statements can also link different aspects of language education, such as curricula, textbooks, and assessments.

The horizontal dimension of the CEFR consists of taxonomies or descriptions of different types of contexts of language use. These include domains (personal, public, occupational, educational) and specific situations of language use within domains; themes (e.g., daily life, travel, education); communicative tasks and purposes (e.g., understanding instructions, making inquiries about work); activities (e.g., reading correspondence, speaking from notes); strategies (e.g., inferring from context); texts (e.g., text types); and conditions and constraints of language use. In addition, the CEFR gives an account of different general and language competences. The former include, for example, the ability to learn and study, which is essential for lifelong learning. The latter cover linguistic, sociolinguistic, and pragmatic competences, which are obviously based on theories of communicative competence developed in applied linguistics.

Impact of the CEFR

The Framework has had considerable impact on language education in Europe—and beyond, as indicated by its translation into several non-European languages. However, its influence varies between countries and areas of language education. The CEFR has had a significant effect on European-level language policies: recently, the Council of Europe issued a resolution (CoE, 2008) recommending that its member states utilize the CEFR more in their educational systems. Also, the European Union considers the CEFR compatible with its language policies and has supported several related projects (Little, 2007, p. 647), including its own major study of foreign language proficiency in secondary education (Jones & Saville, 2009).

Of the areas of language education, CEFR impact has been strongest in language assessment. The international examinations, in particular, have quickly aligned themselves with the CEFR levels (Little, 2007, p. 648); impact on national examinations has been more varied (see Eckes et al., 2005, for details). The Framework’s influence on curricula and textbooks has also been quite considerable but, again, highly variable. In some countries, such as France and Finland, the CEFR has profoundly shaped national curricula (Bonnet, 2007; Hildén & Takala, 2007) but in others it has been ignored so far. In contrast, the role of the CEFR in teacher education and especially classrooms has been modest (Jones & Saville, 2009, p. 54), except perhaps via the European Language Portfolio (Little, 2007, p. 649; see also the examples described in the “Case studies” of the use of the CEFR found at www.coe.int/portfolio).

The view that the impact of the CEFR has been smallest in the language classroom is shared by North (2007, p. 659), who estimates that the Framework’s aim of encouraging “practitioners to reflect on their current practice, particularly to analyzing practical language learning needs, setting objectives, and tracking progress” has not been achieved. However,

much more progress has been made in establishing “a common metalanguage to talk about objectives and assessment,” and in agreeing on common reference points (North, 2007). According to North, the most significant effect of the CEFR is that people working in different pedagogic cultures and areas of language education now understand each other much better.

An important change that the CEFR has brought about in many curricula and assessments is that language proficiency is no longer defined only in terms of grammar and vocabulary—not even as functions and notions—but also as qualitatively and quantitatively different stages of development. Furthermore, criterion referencing is becoming more common in assessment: that is, learners are assessed not by comparing them with each other but with reference to what they can actually do, as described in the CEFR levels.

Space does not allow a detailed treatment of the many applications that have clarified and illustrated the Framework or mediated it to language pedagogy and assessment (see Little, 2006, and the CoE Language Policy Division’s Web site at www.coe.int/lang for more information). Perhaps the single most important and widespread application of the CEFR is the European Language Portfolio (ELP), which makes use of both the horizontal and vertical dimensions of the CEFR and combines learning, teaching, and assessment. The ELP helps language learners to become more autonomous, self-reflective, and capable of setting their own goals and assessing their progress toward those goals with the help of CEFR scales and “can do” statements. The portfolio is also used to record the learner’s linguistic achievements, both formal and informal. It thus supports plurilingualism, partial competences, and lifelong learning, which are all central to the CEFR (cf. Little, 2005, 2006, 2007; www.coe.int/portfolio). The Council has validated about 100 different ELPs for a range of levels and types of language education. However, it is not known how many teachers and learners actually use them; it appears that an ELP needs integration into the curriculum if it is to be used on a continuous basis (Little, 2007, p. 652).

Another major development that has acquainted considerable numbers of learners with the CEFR is DIALANG (www.dialang.org). DIALANG is a free, Internet-based language assessment system in 14 languages based on the CEFR; it provides learners with feedback on the strengths and weaknesses in their proficiency (Alderson, 2005). To a considerable extent it too integrates learning with assessment (and with teaching, depending on how it is used). Importantly, it was the first professionally developed assessment system whose content was based on the CEFR categories of functions, communicative activities, texts, and so forth. It was also the first to design procedures for linking test results with the CEFR levels. About 50,000–100,000 persons take DIALANG tests each year, which means that it has served as a practical introduction to the CEFR for hundreds of thousands of learners so far.

Finally, an important further impact of the CEFR should be noted. The challenges in applying the Framework have also benefited research. Aligning different areas of language education with each other is now more advanced, especially in assessment (cf. the *Manual*; CoE, 2004/2009). More generally in applied linguistics, there is now renewed interest in studying how linguistic forms and functions relate, which is needed when language-specific versions of the CEFR are developed (e.g., Bartning, Martin, & Vedder, 2010). Furthermore, DIALANG, an application of CEFR, led to new openings in diagnosing L2 development and its problems (Alderson, 2005).

Issues and Challenges

Although the CEFR has been welcomed by many it has also engendered criticism and even fears. The perceived problems with the CEFR can be divided into two related types: issues with the document itself and issues with its use.

The CEFR is a long, extensive document because it aims to cover so much of what is involved in using and learning languages. Thus, anybody wishing to understand the Framework needs to spend considerable time studying it, which likely means that most nonlanguage specialists, many of whom nevertheless make policy, admission and other decisions with reference to the CEFR, never actually read it properly. The CEFR is also criticized for being difficult to understand because of vague and imprecise expressions in places (e.g., Alderson, 2007, p. 661). Responses to a survey of 30 CoE member states indicated that there is indeed a need for a reader-friendly summary of the CEFR (Martyniuk & Noijons, 2007, p. 8).

Some researchers criticize the construct validity of the CEFR scales because of the way they were designed (Fulcher, 2004) or because they are not based on findings from second language acquisition research on how proficiency develops (Hulstijn, 2007).

Certain problems with the CEFR relate to imbalance in the quality of its scales and descriptors. First, although many CEFR scales have a sound empirical basis, some do not. Spoken interaction and production are elaborated and empirically scaled but writing, reading, and listening scales have a weaker empirical basis. Definitions of comprehension, in particular, have been criticized for not making use of relevant theory and research (Alderson, 2007, p. 661). More generally, the CEFR is stronger in describing interactive aspects of proficiency than psycholinguistic and cognitive aspects of language use (Weir, 2005, p. 294). Second, the lower part of the scale (A1–B2) is better defined than the two highest levels, C1 and C2; many C2 descriptors, in particular, have no empirical basis (North, 2007, p. 657). Supplementary documents elaborate A1–B2 (i.e., Breakthrough, Waystage, Threshold, and Vantage documents) but detailed definitions of C1 and C2 are only now emerging (see Bartning et al., 2010; North's compilation of C1–C2 descriptors at the European Association for Language Testing Assessment Web site at www.ealta.eu.org/resources.htm; the Profile Deutsch project at www.goethe.de/lhr/prj/prd/deindex.htm; the English Profile project at www.englishprofile.org/).

A further imbalance in the CEFR is that it does not properly address lingua franca use of language or contexts in which two or more languages are used simultaneously. The implicit assumption appears to be that languages are used between native and non-native speakers, and that only one language at a time is used.

The second set of issues concerns the use of the CEFR. Its high international profile has led to criticisms that the CEFR is increasingly being used as a tool of power and centralized control, and as an instrument for harmonization that decreases diversity in language teaching and assessment (e.g., Fulcher, 2004). Claims of linkage to the CEFR may often be made for commercial reasons, simply to promote the sales of courses, textbooks, and tests without empirical backing (cf. CoE *Manual*, CoE, 2004/2009) or adherence to the values and concepts underlying the CEFR (Alderson, 2007, p. 661; CoE, 2008, p. 9). This has led to calls for the Council or some other international body to validate such claims (Alderson, 2007, p. 662), possibly similarly to the validation of European Language Portfolios by the CoE.

Additional challenges concern the use of the CEFR for purposes and audiences it was not originally intended for. It was designed with adults' needs in mind, although learners as young as 15 or 16 were involved in constructing the descriptive scales. Thus, recent applications of the CEFR in curricula for young learners (e.g. Little, 2006; Hildén & Takala, 2007) have added material relevant for children to the descriptions. Further new areas include higher education and the teaching and assessing of language for specific purposes. Here, too, new content needs to be added to the CEFR's descriptive categories and scales. Recently, the use of the CEFR in first language education has also been investigated (North, 2007). Little is yet known about the success of all these new extensions to the Framework coverage.

Given the influence of the CEFR in language testing, it is somewhat ironic that the Framework has turned out to be inadequate as a basis for test design and even for linking purposes (Weir, 2005; Alderson et al., 2006). Consequently, a manual to guide the linking of assessments with the CEFR has been created (CoE, 2004/2009), as well as specific tools to help to analyze test content with reference to the CEFR (e.g., Alderson et al., 2006). Importantly, benchmark examples of speaking and writing performances, and comprehension test items have been published by the CoE to illustrate the reference levels for both pedagogic and assessment purposes. Conveniently, the most robust multilingual speaking samples are available online at www.ciep.fr/publi_evalcert/dvd-productions-orales-cecrl/index.php.

Finally, CEFR users face the neglected question of evaluating to what extent the content of their curricula, textbooks, tests, and so on are aligned with the content of the Framework (Kaftandjieva, 2007). Alignment with the CEFR scale can be complex but procedures nevertheless exist for estimating how successful such (vertical) linking is. In contrast, procedures for estimating successful horizontal content alignment are lacking. Even the *Manual* (CoE, 2004/2009) only offers procedures for describing a test or other content in terms of CEFR content categories. It is possible that the open-ended nature of the CEFR makes it difficult to estimate the adequacy of content alignment, but methods have been developed elsewhere that could be explored for the CEFR (see Kaftandjieva, 2007). Until then, uncertainly lingers with claims of linkage based only on vertical linking with the CEFR.

The Future of the CEFR

The impact of the CEFR is likely to remain strong in Europe and beyond despite occasional criticisms of, for instance, its harmonizing effects, and even instances of misuse. Its influence is increasing with every new purpose and context in which it is used. Particularly important in this respect will be the European Survey of Language Competences by the European Union, because the study makes extensive use of CEFR content and levels (see Jones & Saville, 2009).

As described above, the CEFR is used for so many purposes that, inevitably, its content is not sufficient for all purposes. There are at least two ways to address this: either to design an updated version of the CEFR, or to continue to create external resources—such as the ELP—to complement the Framework. Of course, a combination of the two approaches is also possible. It is not known if and when new versions of the CEFR might be designed; this may be a largely political decision to be made by the CoE member states. In contrast, the proliferation of external resources is likely to continue in the future.

As mentioned above, surveys of users indicate that the Framework is not easy to understand in places. New CEFR-related materials might, therefore, include some simplified versions of the Framework or detailed guidelines on its use and interpretation.

Since the wording of some descriptors has been shown to be problematic (Alderson et al., 2006), a revision of the “can do” statements might also be considered. That would, however, require a new major study and recalibration of the statements; this might be complemented by other empirical approaches recommended in, for example, Hulstijn (2007). Probably the nonempirical CEFR descriptors (North, 2007, p. 657) would also be included in the study.

The Framework will continue to be applied in new contexts, most importantly for young learners and in first language education (North, 2007). There will also be further language-specific elaborations of the linguistic, notional, and cultural content of the CEFR levels (cf. Little, 2007, p. 649) and research that aims at validating such elaborations (cf. Little, 2007, p. 649; Bartning et al., 2010).

The CEFR has clearly made a major impact on national and international policy making in Europe. An obvious future development is to strengthen its current limited role at the classroom level. This would require that curricula, textbooks, teacher training programs, and local tests embrace the goals and view of language of the CEFR more widely and thoroughly than is currently the case. Only in that way can the aims of the CEFR really be achieved.

Community Interpreting

SONJA PÖLLABAUER

Community interpreting (CI) refers to interpreting in public service institutions and differs from other types of interpreting in a number of aspects (e.g., mode of delivery, interaction situation, level of formality/orality present, level of interpreter involvement, status and roles of the participants, level of professionalization, and power asymmetries) (Hale, 2007, p. 31). Compared to conference interpreting, which has achieved the highest level of professionalization within the interpreting world since the 1950s (Pöchhacker, 2004, p. 29), CI is sometimes described as “the poor relation” (Mason, 2001, p. i), a phrase which reflects the status CI has had in the interpreting community until recently. In spite of its low prestige, CI can be said to be one of the most common and oldest types of interpreting (Roberts, 2002, p. 157). Through the centuries, interpreters have had to bridge communication barriers between speakers of different languages and cultures. In interpreting studies (IS), CI has long been neglected. Throughout the 1990s it has gradually become an accepted field of research (Pöchhacker, 2004, pp. 28–9). With respect to practice and training though, its professionalization and acceptance among practitioners, clients, and the public still varies, with a high level of service provision in only a few pioneer countries and the majority of countries lagging behind. This entry will provide an overview of different aspects of CI, the state of training and CI research. It attempts to address both spoken and signed language (SL) interpreting, specifically highlighting aspects in which SL, which enjoys a higher degree of professionalization, differs from spoken-language interpreting.

Community Interpreting: Definition and Labeling

CI differs from “international” (conference/diplomatic) interpreting in that it takes place “within the community” (“intra-social” interpreting) (Pöchhacker, 2004, p. 16). It can be defined as interpreting between individuals (migrants, refugees, members of minority and indigenous groups, occasionally tourists or other foreign-language visitors) and officials of public service institutions (legal, medical, therapeutic, and social settings) in a given society. Typical venues are police stations, emergency rooms, hospital wards, doctors’ offices, immigration and social service departments, schools, and welfare and community centers.

The term CI is often used in juxtaposition to the more prestigious conference interpreting, with other types (business, diplomatic) ranging somewhere between these two poles. It is also used as an umbrella term for different types of interpreting in public settings (public service, legal, medical interpreting) (Roberts, 1997, p. 9). Court interpreting is sometimes (especially in countries with a low level of professionalization), though not always, regarded as part of CI (Pöchhacker, 2004, p. 30). If it is seen as separate, other extra-court “legal” interpreting assignments may nonetheless count as CI and often show the same poor working conditions (Ozolins, 2010, p. 199).

Around the world, this type of interpreting is discussed under different labels, which are not always used synonymously (Hale, 2007, pp. 27–30): *Community interpreting* is often, though not exclusively, used in Europe and the USA; the UK switched to *public service interpreting* as the qualifier “community” became too confusing within a larger EU context

(Corsellis, 2008, p. 7), and, some feared, might also be confused with *community work* and thus perpetuate the notion that CI involves unpaid ad hoc services rendered by untrained volunteers (Bowen, 1999, p. 319). Other used terms are *dialogue interpreting*, *liaison interpreting*, *cultural interpreting*, *community-based interpreting* (Roberts, 2002, pp. 158–61) (the list is not exhaustive). Non-English-speaking countries often borrow the English terms (typically “community interpreting”), or coin loan words on the basis of the English labels, for example, *interprétation sociale*, *interprétation communautaire*, *interprétation en milieu social*, *interprétariat* in France, *interpretación comunitaria*, *interpretación social*, *interpretación (e traducción) en los servicios públicos* in Spain (Bastin, 2001), *Kommunaldolmetschen* in Austria (Pöchhacker, 2000, p. 39), or *mediatore linguistico-culturale* in Italy (Pöchhacker, 2008, p. 22). Some simply call it *interpreting* without an additional qualifier and have pled for an end to this “battle over what could be called ‘adjectival interpreting’” (Ozolins, 2000, p. 30).

Though it is true that CI is simply interpreting, it certainly is not easier than other types of interpreting but can even be more risky due to the potential consequences of interventions and distortions in accuracy (Hale, 2007, p. 32). In 1995, Brian Harris opened the First International Conference on Interpreting in Legal, Health, and Social Service Settings in Toronto, claiming: “Community Interpreting is where the action is” (Community interpreting, 1995, p. 14). This statement reflects very well what makes CI different: Interpreters are potentially faced with highly emotional, high-risk situations over which they have low control (Dean & Pollard, 2001). Community interpreters often render private, and intimate issues into another language. In such encounters, much is at stake, as Smirnov points out: “Sadly enough it is not the life of an interpreter, but that of his client that may become a price paid for a poor rendition” (1997, p. 215).

Characteristics of Community Interpreting

CI differs from other types of interpreting in a number of specific parameters.

Mode of Delivery

Consecutive interpreting (with or without note-taking) is typically used for spoken-language encounters, and simultaneous or consecutive interpretation for sign language contributions (Russell, 2005). Chuchotage (whispered interpretation), a type of simultaneous interpreting, and sight translation (for the translation of written material) are also used frequently (Hale, 2007, p. 32). Phone interpreting has been employed since the 1970s (Pöchhacker, 2004, p. 30); recently new techniques (video interpreting, remote simultaneous interpreting, VoIP interpreting) have also been tested in CI (legal and health-care) settings (Korak, 2010, pp. 19–22). Especially for SL interpreting video interpreting has become a growth market (National Association of the Deaf, 2011). CI encounters are usually bidirectional, that is, interpreters have to translate into both their working languages. In spoken-language interpreting, interpreters do not work in teams as in conference settings, but are almost always on their own. In SL interpreting, interpreters also often work in teams (Jones, 2007).

Level of Formality/Orality

Exchanges in CI settings are usually dialogical with two or more speakers interacting. This may entail specific problems for the interpreters with respect to discourse management (e.g., overlapping talk, confusion in turn taking, specific cross-cultural communicative strategies). The “texts” community interpreters render are—unlike monologic, prepared talk (“written to be spoken”)—usually shorter patches of unplanned speech of a wide

variety of register, including slang, dialects, and nonstandard language use (Hale, 2007, pp. 31–2). Encounters may be both highly formal and informal, with different levels of technicality. The languages used in CI are often languages of limited diffusion or indigenous languages (Ozolins, 2000, p. 21) with a concomitant low status of its speakers and low availability of (qualified) interpreters for these languages, as opposed to so-called “world languages” often used in other settings.

Level of Intimacy/Emotionality

In CI, delicate and personal matters are on the agenda, and interpreters cannot hide behind the protective walls of an interpreting booth. They are right in the heart of “action” and sometimes become the center of attention, criticism, or anger themselves. Interpreters are faced with “disease, poverty, migration, labour, human rights” (Setton, 2007, p. 58) from a very different perspective. Community interpreters also have a gate-keeping function: They are mediators (“gate-keepers”) between the host-country officials, who have the power to grant or withhold certain services, and the individuals applying for these services (information, subsidies, etc.).

Level of Involvement

CI takes place in face-to-face settings with a (usually) limited number of participants (prototypically three). Encounters often evolve from dyadic to triadic “three-way exchanges”: Interpreters intervene actively and frequently turn into a third party in the interaction (Mason, 2001, p. ii). The often assumed “invisibility” of interpreters turns out to be a myth: “the interpreter cannot avoid becoming involved as a participant, whether through their own translational filter (e.g. subtle modifications to the register or pragmatics of source speech) or through the need to comment on their own or others’ linguistic behaviour” (Mason, 2001, p. ii). Performance standards applied to other settings cannot be automatically transferred to CI (Setton, 2007, p. 59). Though the principles of neutrality and detachment, which are common and commonly accepted precepts in ethical codes for interpreters, should principally also be applicable to CI, this is in fact not always true. In CI settings, interpreters often have problems defining their role and staying within the confines of their role: Aspects of neutrality/involvement and attachment/detachment have been a major issue of debate among practitioners and in research. This is partly caused and certainly exacerbated by the fact that (at least in spoken-language interpreting) community interpreters are not always trained interpreters with a formal qualification but very often “natural interpreters” (Harris, 1977), that is, unpaid and untrained individuals who are called upon to interpret on the basis of their presumed language competence (e.g., family members, friends, strangers, and co-workers). The use of such lay interpreters is still widespread in CI, especially in countries with a low degree of professionalization of CI, but sometimes even in countries with a more professionalized stance toward interpreting. Even children are used (in some settings on a regular basis) as interpreters—with potentially harmful consequences (Pöchhacker, 2000, p. 175).

The interpreters’ roles in these interaction constellations are very complex: Community interpreters always work for two clients simultaneously. They may be required to simultaneously serve both sides and “help” them, meaning they “can, from two opposing points of view, be regarded as potential renegades” (Wadensjö, 1998, p. 34). Interpreters, especially untrained interpreters, often exceed their authority: There are accounts of interpreters working actively “against” one side, distorting information, and intervening unprofessionally (Barsky, 1994, p. 43 & *passim*). Clients sometimes mistrust interpreters due to their affiliation to a specific ethnic group (Barsky, 1994, p. 48), their language (language of the “enemy”), their “wrong” age (too old, too young) or gender (Pöllabauer, 2005, pp. 104–7). In the case

4 COMMUNITY INTERPRETING

of such basic mistrust and prejudice, important details may well remain unsaid which may have serious consequences for the outcome of an interaction.

Level of Non-Equality/Power Asymmetries

Many CI settings are characterized by an inherent power asymmetry: The mechanism and institutional (sociocultural) “rules” of the host country are unknown and the entire system and situation potentially bewildering to migrants or members of minority groups (who may sometimes have very little schooling and be illiterate). Very often, they are required to follow Kafkaesque, implicit, and unspoken rules to get along. Culture-specific forms of behavior and host-country communicative patterns may appear strange to them, which is why community interpreters are also sometimes called upon to “help” these clients and explain cultural differences (“cultural mediation” or “cultural interpreting”) (Pöchhacker, 2000, p. 241). There is no consensus, however, as to the extent to which cultural mediation, which often involves more than interpreting, is deemed adequate; in some fields and/or countries, the role of interpreters as cultural mediators is not regarded as being acceptable, while in others (e.g., Italy) it has recently even been advocated by some institutions, mostly in the health-care sector (Pöchhacker, 2008).

Conflicting Goals, Social Tension, and Lack of Awareness

Speakers in CI settings often have conflicting goals (e.g., asylum-seeker vs. asylum-granting authority). Resolving vital requests for one party may involve curtailing the other party’s interests. CI is also a field in which social tensions, racial prejudice, and ethnic tensions may have a considerable influence on communicative encounters and their outcome: The provision of adequate language services for migrants is only seldom a top priority for policy makers and often met with low acceptance among the public; immigration issues are highly controversial in some countries; and members of minority groups are faced with antagonism and prejudice factors, which bear down on the work of interpreters.

Interpreting Practice and Service Provision

In only a few countries is CI a fully fledged profession. Compared to other forms of interpreting, CI often remains a low-status type of interpreting with little training among practitioners, lack of recognition, and low remuneration (Pöchhacker, 2004, p. 30). The provision of CI services (or the lack of such services) clearly reflects a society’s stance toward equal access, civil rights, and immigration (Wadensjö, 2001, p. 37). A higher level of professionalization has been achieved in SL interpreting (Napier, 2004).

On a national level, professionalization is often triggered by the introduction of antidiscriminatory legislation. The Court Interpreters Act led, for instance, to the professionalization of court interpreting in the US in the 1970s; at the same time, new legislation prompted the professionalization of SL interpreting and the development of a national association of interpreters (Registry of Interpreters for the Deaf, RID) (Pöchhacker, 2004, p. 29). Apart from these two trailblazing events, however, professionalization in CI has, if at all, mostly been achieved in the legal and medical fields (Pöchhacker, 2004, p. 30), and mostly in countries with “an explicit immigration policy” (p. 30) and a climate in which fair and equal access to services and the availability of adequate interpreting services are considered important and recognized by the majority of the population (Wadensjö, 2001, p. 34). In many countries worldwide, the situation is less favorable: Institutions continue to use lay interpreters with no or hardly any training, who are recruited on an individual, ad hoc basis, often with no payment at all. There are no or highly divergent training measures, and no accreditation systems, professional guidelines, or professional organizations. The

interpreting market is hardly regulated, and anyone can serve as an interpreter on the basis of his or her alleged interpreting skills. There are few to no quality controls and little awareness as to the dangers of using untrained interpreters (Ozolins, 2000, 2010) even though certification/credentialing would be highly important.

In terms of the spectrum of service provision (Ozolins, 2000), on the one end, there are a very few countries that provide fully comprehensive interpreting services, including full-scale training (possibly even train-the-trainer and train-the-user programs), national registers of interpreters, accreditation, a professional body with agreed performance standards, adequate remuneration, and political support for equal access and service provision for foreign-language-speaking individuals; this mainly applies to “pioneer” countries such as Australia and Sweden, or the US and Canada for SL interpreting. Countries which completely “deny the existence of multilingual communication issues” (Ozolins, 2000, p. 21) are at the opposite end of the spectrum. Between these two poles, a large number of countries rely on diverse ad hoc or generic approaches with institutions trying to cover language barriers in different (often highly divergent) ways, but with little political and legislative support.

Training Situation

Training is often regarded as the key to professional service provision. In CI, it nonetheless remains one of the problem areas, with little or no training available for spoken-language interpreting in many countries. Only pioneering countries such as Australia or Sweden have implemented training programs and interpreting services on a large scale as early as in the 1960s and 1970s (Pöschhacker, 2004, p. 30). Today, the training spectrum ranges from nonexistent in some countries (usually countries with little immigration or acceptance of immigration), ad hoc training measures and semi-institutionalized training, to full-scale, comprehensive training provision (the exception) (Ozolins, 2000). The training situation differs with respect to SL interpreting: SL interpreter training is available in several countries worldwide (also at a university level) (Napier, 2004).

With respect to spoken-language interpreting, training often takes place outside academic settings: University or college training programs (usually at the postgraduate level) are underrepresented. Higher education institutions have only recently started to integrate CI into their curricula (often within single seminars or modules), which previously had focused primarily on conference interpreting. Training concepts are highly divergent with regard to duration, content, admission criteria, testing, teaching approaches, language combinations, degrees awarded, and so forth (Hale, 2007, p. 168). In a nonacademic context, training is offered by interpreting services and user institutions for their (in-house) interpreters. Distance/online training has been explored by some training institutions (Roberts, 2002, pp. 170–1).

Some of the challenges in CI training are: a lack of qualified trainers, which has triggered the development of train-the-trainer courses (Corsellis, 2008, p. 65); problems in attracting students with adequate language/cultural skills (Hale, 2007, p. 169); deciding on the most relevant content of training measures, and adequate teaching methods (Pöschhacker, 2004, pp. 186–7); lack of awareness among users as to the importance of using qualified interpreters, leading to the establishment of train-the-user courses (Corsellis, 2008, pp. 118–49); the development of adequate screening and assessment methods (Corsellis, 2008, pp. 60–9).

Research

Since the 1990s CI has established itself as a valid field of IS, with the “social turn” in IS leading to a shift from cognition to interaction (Pöschhacker, 2008, p. 39). Before that,

beginning in the 1950s, interpreting research had mainly focused on conference interpreting. Research on CI was fuelled by the Critical Link conference series (starting in 1995, with successive conferences in 1998, 2001, 2004, 2007, and 2010), which has brought together practitioners, trainers, and researchers.

CI research has always been attractive to scholars from other disciplines and been dealt with from different theoretical/disciplinary angles (e.g., cultural studies, discourse studies, linguistics, pragmatics, sociology) (Pöchhacker, 2004, pp. 47–60). Some of the most influential publications have been written by authors with a different disciplinary background, for example the seminal publications by Berk-Seligson (1990), Wadensjö (1998), Barsky (1994) on spoken-language interpreting, and Metzger (1999) and Roy (2000) on SL interpreting; these latter two especially have succeeded in bridging the gap between research on SL interpreting and spoken-language interpreting with their broad focus and wide reception in IS. CI research broadly focuses on diverse aspects of interaction and the dynamics of mediated discourse.

Comparative Phonetics and Phonology

RACHEL HAYES-HARB

Introduction

It has long been observed that non-native accents exhibited by second language learners are not random in their features; rather their features seem to be predictable at least in part from the native language(s) of the learner. That is, native Japanese speakers learning English tend to produce accented English speech that is typical of native Japanese speakers, and that also appears to reflect the transfer of aspects of the phonetics and phonology of Japanese into their English speech. For example, it is not uncommon for native Japanese speakers to produce the English words “read” and “lead” as homophones. Japanese does not have the phonemes /r/ and /l/; instead, Japanese has a single liquid category, which native Japanese speakers presumably transfer into their English productions, replacing both English /r/ and /l/. Similarly, as a group, native English speakers learning Spanish tend to produce characteristically English-accented Spanish. For example, in English, syllable-initial voiceless stop consonants are aspirated (as in [t^hu] “two”), while in Spanish they are not (e.g., [tu] “you”). Native English speakers typically inappropriately aspirate voiceless stop consonants when speaking Spanish, presumably as a result of the transfer of an aspiration process from their native English to Spanish.

The observation that the native-language sound system seems to impact the second language sound system is not in fact a matter of any serious controversy in the second language acquisition literature. On the other hand, the extent of this impact, the reasons for it, and how non-native accents can be overcome by learners are topics of debate among second language acquisition researchers, and have inspired a large body of research spanning several decades. The focus of this entry will be on the historical progression of theories of the effects of the relationship between native-language and second language sound systems on second language acquisition, beginning with the contrastive analysis hypothesis and its revisions, and concluding with current models of second language speech perception and production.

The Contrastive Analysis Hypothesis

In 1957, Skinner published *Verbal Behavior*, wherein he proposed that language acquisition was a process of acquiring a set of habits through learning and reinforcement, reflecting the then-current philosophy of psychology known as behaviorism. In the same year, Lado published *Linguistics Across Cultures: Applied Linguistics for Language Teachers*, in which he detailed what became known as the contrastive analysis hypothesis. Lado’s (1957) hypothesis was heavily influenced by Skinner’s theory of verbal behavior, and also by earlier comparative linguistics work by Fries (1945), Weinreich (1953), Haugen (1956), and others. According to Lado (1957), the linguistic habits developed over the course of native-language acquisition are carried over into the second language: “Probably because the use of the sound system of a language operates as a system of automatic and semiautomatic habits, it is extremely difficult to change anything in that system” (p. 11).

2 COMPARATIVE PHONETICS AND PHONOLOGY

In this way, Lado (1957) predicted that all errors committed by second language learners could be explained in terms of differences between the native and second languages. Specifically, “those elements that are similar to [the learner’s] native language will be simple . . . , and those elements that are different will be difficult” (1957, p. 2).

Lado (1957) further detailed a procedure for undertaking the comparison of native and second language sound systems, grammatical structures, vocabulary systems, writing systems, and cultures. The procedure for the comparison of sound systems can be roughly summarized as follows:

1. Compare the individual phonemes of the two languages:
 - a. Does the native language have a phonetically similar phoneme?
E.g., English has the phoneme /h/; Portuguese does not (p. 13).
 - b. Are the variants of the phonemes similar in both languages?
Example: The Spanish phoneme /d/ can surface as a fricative; English /d/ cannot (pp. 14–15).
 - c. Are the phonemes and their variants similarly distributed?
E.g., The French phoneme /zh/ can appear word-initially; English /zh/ cannot (p. 17).
2. Compare the allowable phoneme sequences in the two languages along with their distributions:
E.g., English allows syllable-initial /sp, st, sk/ clusters; Spanish does not (pp. 17–18).
3. Compare the stress and rhythm patterns of the two languages:
E.g., English allows weak stress (i.e., unstressed syllables); Spanish does not (pp. 33–4).
4. Compare the tone/intonation patterns of the two languages:
E.g., Spanish matter-of-fact statements have a low-mid-low intonation pattern; English matter-of-fact statements have a mid-high-low intonation pattern (p. 44).
E.g., In Thai, pitch is associated with morphemes and words; in English, pitch is determined by sentence-level intonation patterns (p. 45).

The product of a contrastive analysis, then, is a list of similarities and differences between the two languages, which can presumably be used to predict which second language structures a learner will find relatively easy or relatively difficult. For example, because English allows syllable-initial /sp, st, sk/ clusters but Spanish does not, native speakers of Spanish should have difficulty learning to produce these clusters in English, and indeed it is widely documented that they do (see, e.g., Altenberg, 2005). According to Lado, the predicted ease and difficulty of second language structures can directly inform second language pedagogy:

Even though the process of comparing two sound systems must of necessity be tedious, dry, and abstract, the results obtained are of great practical use for the preparation of textbooks, tests, and exercises to supplement inadequate materials, and for the evaluation of materials and the diagnosis of student problems. (Lado, 1957, p. 12)

Lado thus asserted that predictions about the structures that are likely to cause errors can lead to teaching materials and methods that anticipate and directly address the errors. Throughout the 1960s, the contrastive analysis hypothesis was intensely popular among language teachers, and was a major theoretical underpinning of what became known as the audio-lingual method of language teaching. In the audio-lingual method, the presentation of second language materials was determined by contrastive analysis, with a focus on structures that were different between the native and second languages (and therefore predicted to be more difficult for learners) in order to help students overcome “incorrect habits” transferred from the native language. The audio-lingual method fell generally out

of favor during the 1970s, as evidence counter to the contrastive analysis hypothesis in its original form mounted.

The version of the contrastive analysis hypothesis originally posited by Lado in 1957 has since become known as the strong version of the contrastive analysis hypothesis. This strong version is characterized by a priori comparison of the native and second languages with the goal of predicting learner difficulties. However, it gradually became clear that:

- Learners often do not make the errors predicted by the contrastive analysis hypothesis. E.g., Native English speakers discriminate a Zulu click contrast with native-like accuracy. Contrastive analysis predicts that this should be a source of learner error: English does not have any click consonants (Best, McRoberts, & Sithole, 1988).
- Learners often make errors that are not predicted by the contrastive analysis hypothesis. E.g., Native speakers of Mandarin sometimes devoice English word-final voiced obstruents. Contrastive analysis does not predict this error: Mandarin does not allow word-final obstruents and does not have a word-final obstruent devoicing rule (see, e.g., Broselow, Chen, & Wang, 1998).

Wardhaugh (1970) detailed what is known as the weak version of the contrastive analysis hypothesis; in this version, comparison of the native and second languages can be used to help explain learner errors in an a posteriori fashion. Proponents of this version of the contrastive analysis hypothesis analyze actual learner errors in light of similarities and differences between the first and second languages in order to determine possible sources for the errors, using methods from the field of error analysis (see, e.g., Corder, 1967). While the a posteriori approach to contrastive analysis at first appears to solve the two problems with a priori contrastive analysis listed above, in fact, as Schachter (1974) pointed out, error analysis can only be used to identify and analyze errors that learners actually produce, and ignores potential errors that learners do not make because they avoid difficult structures. Schachter therefore advocated the use of a combination of a priori contrastive analysis and error analysis in order to better understand second language sound patterns.

Revisions to the Contrastive Analysis Hypothesis

Since the 1960s, second language researchers have proposed a number of revisions to the contrastive analysis hypothesis. There are several reasons for this development. First, it was noted that the contrastive analysis hypothesis as discussed thus far does not, in either the strong or weak versions, provide an explanation for the relative difficulty of second language structures for learners. However, not all novel second language structures pose equal difficulty for learners. For example, Eckman details the case of word-final obstruent voicing in German and English. While English allows voiced obstruents word-initially, -medially, and -finally, German only allows voiced obstruents in the word-initial and -medial positions (that is, underlyingly voiced obstruents are devoiced word-finally). The CAH predicts that native English speakers learning German should have the same degree of difficulty learning to devoice German word-final voiced obstruents as do native German speakers learning to produce the voiced–voiceless contrast word-finally in English. Instead, however, native English speakers appear to have relatively little difficulty learning the German devoicing rule, while native German speakers have relatively more difficulty learning to produce the word-final voicing contrast.

In addition to the inadequacy of traditional contrastive analysis to explain relative learner difficulty, revisions to the CAH also reflected the “Chomskyan revolution” in the field of theoretical linguistics, which began in the late 1950s and resulted in a move away from behaviorism toward an innatist view of language. A central claim of Chomsky’s was that

4 COMPARATIVE PHONETICS AND PHONOLOGY

all language was governed by an innate endowment known as universal grammar, which determined what was and was not possible in language, and also the relative markedness of linguistic structures. Selinker's (1972) interlanguage hypothesis represents the application of Chomskyan linguistics to second language acquisition theory—Selinker proposed that the language of learners was not simply an imperfect approximation of the second language, but rather an emerging linguistic system that was subject to the principles of universal grammar. These developments in linguistic theory and second language acquisition theory paved the way for revisions to the contrastive analysis hypothesis that improved its ability to account for observed learner data. For example, Eckman (1977) proposed that incorporating the notion of markedness into the contrastive analysis hypothesis can lead to an explanation for the relative difficulty of second language structures, in the form of the markedness differential hypothesis, where (from Eckman, 1977, p. 321):

1. Those areas of the target language which differ from the native language and are more marked than the native language will be difficult.
2. The relative difficulty of the areas of the target language which are more marked than the native language will correspond to the relative degree of markedness.
3. Those areas of the target language which are different from the native language, but are not more marked than the native language will not be more difficult.

Eckman provided support for the markedness differential hypothesis via the case of the relative difficulty of word-final obstruent voicing in German and English. Using typological evidence, Eckman presented an implicational hierarchy with respect to where languages maintain underlying voicing contrasts in surface forms, indicating that the surface maintenance of an underlying voicing contrast is most marked in word-final position. The relative markedness of the maintenance of the contrast in word-final position therefore renders the English pattern more difficult to learn than the German pattern, accounting for the observed directionality of difficulty. Thus the simple comparison of native and second language structures must be accompanied by a theory of markedness in order to make adequate predictions about second language learner difficulty. While the transfer of native-language structures into the second language continues to be acknowledged as playing an important role in second language acquisition, much research since the 1970s has focused on determining how transfer, in combination with other influences, in particular markedness and developmental effects, determine the structures observed in learner language. Hecht and Mulford (1982) investigated the acquisition of English by a six-year-old native speaker of Icelandic and found that not only did transfer and developmental (i.e., markedness) effects interact in determining acquisition patterns, but that transfer best explained the relative difficulty the learner had with particular segments, and developmental factors best explained sound substitution patterns. Broselow (1984), Broselow and Finer (1991), Hancin-Bhatt and Bhatt (1997), and Broselow, Chen, and Wang (1998), among others, have demonstrated that second language syllable structure is influenced by a sometimes nuanced interaction of transfer and developmental effects.

The Acquisition of Second Language Segments and Systems of Phonological Contrast

The (revised) contrastive analysis hypothesis formed the theoretical foundation, throughout the 1970s and 1980s, for much research investigating the general prediction that second language phonemes that are similar to native-language phonemes will be relatively easy for learners, and that second language phonemes that are different from native-language

phonemes will be relatively difficult to learn. However, the simple similarity/difference between the phonemes of the first and second languages does not adequately account for some second language phenomena. For example, Flege (1987) investigated the production of the French /u/ and /y/ vowels by native English speakers. The French vowel /u/ is acoustically similar to English /u/, and the French vowel /y/ is relatively more different from any English vowel. Therefore, according to the contrastive analysis hypothesis, native English speakers should exhibit more difficulty producing French /y/ than French /u/. In fact, however, Flege found that native English speakers produced French /u/ with higher F2 values than did native French speakers, yet there was no difference between the native English and French speakers when producing French /y/. This finding indicates that when the native and second languages have phones that are similar (but not identical), learners may in fact encounter more difficulty learning to produce them accurately than when native and second language phones are less similar. Flege attributes this phenomenon to what he terms “equivalence classification,” where similarity between native and second language phones prevents L2 learners from developing a separate phonetic category in the second language, resulting in the use of a single, merged category that is used in both the native and second languages, and retains properties of the native-language category. On the other hand, when native and second language phones are sufficiently dissimilar, the learner is free to create a new phonetic category in the second language that closely approximates the second language category. Thus, in the case of equivalence classification, similarity between native and second language sounds leads to greater difficulty for learners than does difference.

In the 1990s and the first decade of the 21st century, researchers became increasingly interested in the types of both similarities and differences that can exist between native and second language sound systems, and ways of assessing similarity and difference. The two most prominent models of non-native speech (perception and/or production) during this time are Flege’s speech learning model (e.g., Flege, 1995) and Best’s perceptual assimilation model (e.g., Best, 1995). While the speech learning model is a model of second language speech learning, and the perceptual assimilation model is a model of cross-language perception, for the purpose of the present discussion, the overlap in their goals is more important than their differences. In both models, success in learning to perceive (and/or produce) the phonological contrasts of a second language will depend (in part) on the perceived relationship between phones in the native and the second languages. In both models, similarity and difference between native and second language phones are assessed via cross-language perception experiments, in which the second language sounds are classified according to native-language phonetic categories, and rated for how well they fit into the native category. In this way, it may be possible to determine the perceived phonetic distances between native and second language phones.

Best (1995) provides a useful typology of the perceptual relationships that can exist between the phonological contrasts of a native and second language, along with predictions of their relative discriminability by non-native listeners (Best, 1995, p. 195):

1. Two-Category Assimilation: Each non-native segment is assimilated to a different native category, and discrimination is expected to be excellent.
2. Category-Goodness Difference: Both non-native sounds are assimilated to the same native category, but they differ in discrepancy from native “ideal”. . . . Discrimination is expected to be moderate to very good, depending on the magnitude of difference in category goodness for each of the non-native sounds.
3. Single-Category Assimilation: Both non-native sounds are assimilated to the same native category, but are equally discrepant from the native “ideal”. . . . Discrimination is expected to be poor. . . .

4. Both Uncategorizable: Both non-native sounds fall within phonetic space but outside of any particular native category, and can vary in their discriminability as uncategorizable speech sounds. Discrimination is expected to range from poor to very good, depending upon their proximity to each other and to native categories. . . .
5. Uncategorized versus Categorized Type: One non-native sound assimilated to a native category, the other falls in phonetic space, outside native categories. Discrimination is expected to be very good.
6. Nonassimilable: Both non-native categories fall outside of speech domain being heard as nonspeech sounds, and the pair can vary in their discriminability as nonspeech sounds; discrimination is expected to be good to very good.

It is thus predicted that extremely sophisticated and nuanced relationships between the sound systems of the native and second languages are what determine the relative difficulty of non-native phonological contrasts, and unlike Lado's (1957) version of the contrastive analysis hypothesis, current models of second language speech do not simply equate similarity with ease, and difference with difficulty. Nonetheless, it is clear that comparison of the native and second language sound systems still plays a crucial role in explaining second language phonetic and phonological phenomena.

Summary and Conclusion

Over the past 50 or so years, there have been several important developments concerning the role of comparative phonetics and phonology in predicting and explaining second language phenomena. The contrastive analysis hypothesis in its original formulation predicted that similarities between the native and second languages would result in ease of acquisition, while differences would lead to learner difficulty. This strong version of the hypothesis became untenable as it was found that it both over- and underpredicted learner errors, leading to a weaker version of the hypothesis where similarities and differences between the native and second languages were useful in the *a posteriori* explanation of learner errors. Further developments in contrastive analysis occurred as researchers noted that a theory of second language acquisition must acknowledge the contributions of markedness and developmental effects, in addition to transfer, to the relative difficulty of second language structures. Finally, over the past twenty or so years, second language speech researchers have focused a great deal of attention on the relative difficulty posed by second language phonological contrasts that differ in their relationships to native-language contrasts, and have proposed a sophisticated set of hypotheses about the relative difficulty of second language contrasts with respect to the relationships between native and second language sounds.

In conclusion, the importance of considering similarities and differences between the phonetics and phonology of the native and second languages in order to make predictions about and/or explain second language phenomena has never been seriously challenged by second language acquisition researchers. However, it has become clear that a simple comparison of the structures of the two languages is insufficient; rather, any adequate account of second language phonetics and phonology must accommodate effects other than transfer (including, but not limited to markedness/developmental effects), and must also acknowledge that similarity and difference between the two languages do not translate straightforwardly into, respectively, ease and difficulty for second language learners.

Comparing Groups With Multiple Dependent Variables

SHAUNA J. SWEET AND ANDRÉ A. RUPP

Multivariate analysis of variance (MANOVA) is a multivariate extension of the general linear model in which a linear combination of p continuous dependent variables is expressed as a function of one or more categorical independent variables/factors that are used to represent different treatments or experimental conditions. One might be interested in, for example, the effect of instructional feedback on second language learners' sociolinguistic competence, where the latter is measured by scores on multiple assessments that measure students' grammatical competence, pragmatic competence, as well as appropriate oral and written production of appropriate linguistic phrases across different real-life contexts. Alternatively, one might be interested in the impact of the availability of different learning resources and type of instruction on students' performance on richly contextualized exams over time. Each of these is illustrative of questions that could be investigated using MANOVA; the first scenario reflects its use in a cross-sectional setting whereas the second reflects its use in a longitudinal setting.

Surveys of peer-reviewed journals in applied linguistics have revealed a dramatic increase in the use of quantitative methodologies generally between 1970 and 1985. MANOVA has been used with increasing frequency in the social sciences since the 1970s, though its use in applied linguistics specifically is not nearly as common as in other domains such as psychology or education. A follow-up review of professional publications between 1991 and 1997 showed an increasing reliance on the use of quantitative methods with MANOVA being the most popular analytic method among them (Henning, 1986; Lazarton, 2002).

Although it is most often advocated for use with experimental designs, MANOVA is an analytic technique that can also be utilized when researchers seek to detect group differences on multiple dependent variables in quasi-experimental or observational studies; a treatment could be self-selected (such as by students' previous exposure to a second language), or groups could be defined by the investigator (for example different proficiency groups). As suggested earlier, MANOVA supports both the analysis of cross-sectional and longitudinal repeated-measures data where a single measurement taken at p time points creates the p dependent variables. As with other general linear models, the use of a MANOVA for analytic purposes does not create causal inferences per se; instead it is the nature of the data-collection design that determines the strength of the inferences that can be made.

The Multivariate Null Hypothesis

MANOVA is typically described as a multivariate extension or multivariate analogue of univariate ANOVA. As with univariate ANOVA models, one can distinguish between one-way, two-way, or k -way models depending on whether one, two, or k categorical predictor variables are included in the model. In a basic one-way ANOVA model, the null hypothesis is that the population mean on some outcome of interest is equal across k groups that are represented by the levels of the single categorical predictor variable in

2 COMPARING GROUPS WITH MULTIPLE DEPENDENT VARIABLES

the model; the alternative hypothesis is that the population mean of at least one group is different from the others:

$$H_0 = \mu_1 = \mu_2 = \cdots = \mu_k$$

In a basic one-way MANOVA model, the null hypothesis concerns the equivalence of the population mean vectors or centroids across the k groups; each vector contains the population means on all p dependent variables:

$$H_0 = \begin{bmatrix} \mu_{11} \\ \mu_{21} \\ \vdots \\ \mu_{p1} \end{bmatrix} = \begin{bmatrix} \mu_{12} \\ \mu_{22} \\ \vdots \\ \mu_{p2} \end{bmatrix} = \cdots = \begin{bmatrix} \mu_{1k} \\ \mu_{2k} \\ \vdots \\ \mu_{pk} \end{bmatrix}$$

The alternative hypothesis is that there is at least one group with a population mean vector that is different from the others.

The Computational Mechanics of MANOVA

In MANOVA the population means for the k groups on the p dependent variables are not compared independently of one another, which would be the case if a sequence of p univariate ANOVAs were conducted. Instead, computational procedures for MANOVA rely on the variance–covariance matrix for the p dependent variables ($X_1, X_2, \dots, X_p$), which are used to construct one or more optimally weighted linear combinations/variates/discriminant functions ($C_1, C_2, \dots, C_m$).

$$\begin{aligned} C_1 &= W_{11}X_{11} + W_{12}X_{12} + \cdots + W_{1p}X_{1p} \\ C_2 &= W_{21}X_{21} + W_{22}X_{22} + \cdots + W_{2p}X_{2p} \\ &\vdots \\ C_m &= W_{m1}X_{m1} + W_{m2}X_{m2} + \cdots + W_{mp}X_{mp} \end{aligned}$$

These combinations can be thought of as a rotation of the original axes of the multivariate space such that differences between the k groups are maximized along these rotated, or newly created, dimensions while correcting for informational redundancy in these variables. MANOVA is thus especially effective for detecting group differences that exist for linear combinations of dependent variables, rather than simply multiple individual variables. As a result, MANOVA can help to separate groups that would be marginally indistinguishable if group mean differences were tested independently on the p variables.

Figure 1 shows this case for $p = 2$ dependent variables. Here, a group difference is difficult to detect with respect to variable X_1 as the two marginal univariate normal distributions overlap quite a bit; a group difference is more easily detectable with respect to variable X_2 as the two marginal univariate normal distributions are more strongly separated; but the key group difference of interest, which exists with respect to both correlated variables X_1 and X_2 , is easiest to detect along a diagonal line that represents a specific linear combination of X_1 and X_2 .

Test Statistics

There are several test statistics that can be used to evaluate the tenability of the multivariate null hypothesis. The F -test statistic that is used in univariate ANOVA models, which is a

Figure 1 Group differences in unidimensional versus two-dimensional space

Table 1 Common multivariate statistics

<i>Statistic</i>	<i>Symbol</i>	<i>Conceptual formula</i>
Wilks's Lambda	Λ	$\frac{SS_{\text{Within on } C_1}}{SS_{\text{Total on } C_1}} + \dots + \frac{SS_{\text{Within on } C_m}}{SS_{\text{Total on } C_m}}$
Pillai-Bartlett Trace	V	$\frac{SS_{\text{Between on } C_1}}{SS_{\text{Total on } C_1}} \times \dots \times \frac{SS_{\text{Between on } C_m}}{SS_{\text{Total on } C_m}}$
Hotelling-Lawley Trace	T	$\frac{SS_{\text{Between on } C_1}}{SS_{\text{Within on } C_1}} + \dots + \frac{SS_{\text{Between on } C_m}}{SS_{\text{Within on } C_m}}$
Roy's Greatest Characteristic Root	θ	$\frac{SS_{\text{Between on } C_1}}{SS_{\text{Total on } C_1}}$

function of the amount of between-group variation that is due to each effect included in the model, cannot be directly used for MANOVA. In MANOVA models, operations are performed on transformations of the observed variance-covariance matrix of the p dependent variables. Specifically, each test statistic is a function of the proportion of the amount of between-group variation along different discriminant functions ($C_1, C_2, \dots, C_m$).

The four most commonly reported multivariate test statistics are Wilks's Lambda, Pillai-Bartlett Trace, Hotelling-Lawley Trace, and Roy's Greatest Characteristic Root. Of these, Wilks's Lambda is the one that is most often reported. As shown in Table 1, each test statistic is calculated by using slightly different pieces of information. Roy's Greatest Characteristic Root reflects the amount of variation captured in only the first discriminant function. The remaining statistics are based on ratios that involve two of the following quantities: the between-group variation, the within-group variation, and the total variation along the m discriminant functions. Among all statistics, Wilks's Lambda offers perhaps the most straightforward interpretation, as it is a direct representation of the proportion of variance that remains unaccounted for by the grouping structure which is induced by the independent variables.

Model Assumptions

Just as with univariate ANOVA, the accuracy of the p -values associated with MANOVA test statistics and the coverage probabilities of associated confidence intervals depends on how well the characteristics of the data satisfy the model assumptions (Bray & Maxwell, 1985; Lattin, Carroll, & Green, 2002). In order for the theoretical sampling distributions for test statistics to be accurate in MANOVA models, it is required that the observations comprise an independent random sample of the population of interest and that the p dependent variables follow a multivariate normal distribution. Logarithmic, arcsine, and similar transformations of individual dependent variables may be used to induce marginal univariate normality, a necessary but not sufficient condition for this assumption to be met.

Two further critical assumptions are that the variance of each of the dependent variables is constant across all k groups, which is identical to univariate ANOVA, and that the covariance between any two dependent variables is constant across all k groups, which is unique to the multivariate context. Box's M Test can be used to test for the homogeneity of the variance-covariance matrices across the k groups, but the test is very sensitive to even small departures from homogeneity and non-normality so that it is rather conservative. In practice, ensuring that groups are of equal size can often help minimize the impact of violating this assumption (Bray & Maxwell, 1985). As with other linear models, the correlation between the categorical predictor variables, also known as multicollinearity, can negatively impact the precision and power of the test statistics. This is not an issue for true designed experiments but can be an issue in the case of quasi-experimental or observational studies where the grouping structure is preexisting, rather than created by design. MANOVA is also particularly sensitive to the presence of outliers, which increases the likelihood of Type I errors (Haase & Ellis, 1987; Cole, Maxwell, Arvey, & Salas, 1994). As with other statistical models that do not involve latent variables, it is assumed that all variables are measured without error.

Power of Test Statistics

The statistical power and the robustness of the four MANOVA test statistics to violations of the model assumptions are two criteria that are helpful for selecting the most appropriate multivariate test statistic in any given situation; Figure 2 shows how the four test statistics perform with respect to these two criteria. There is no single test statistic that is uniformly most powerful. Roy's Greatest Characteristic Root is most powerful when the dependent variables exhibit a concentrated structure such that the between-group variation

Notes: Λ = Wilks's Lambda, V = Pillai's Trace, T = Hotelling's Trace, and θ = Roy's Greatest Root.

Figure 2 Relative robustness and power of common test statistics for MANOVA

is primarily concentrated along a single linear discriminant function of the dependent variables. This situation is rarely encountered in practice, however. When the dependent variables exhibit a diffuse structure and multiple linear discriminant functions are required to capture key patterns in the data, Pillai's Trace and Wilks's Lambda are most powerful (Olson, 1976; Stevens, 1980).

Robustness of Test Statistics

Pillai's Trace and Wilks's Lambda are most robust to violations of statistical assumptions. Pillai's Trace is the only statistic that is robust both to heterogeneity of variance-covariance matrices across groups and to violations of multivariate non-normality. Wilks's Lambda is reasonably robust to violations of multivariate non-normality only. In contrast, Roy's Greatest Root criterion is highly sensitive when any of the statistical assumptions are violated, which is not uncommon in social science research (Olson, 1976; Bray & Maxwell, 1985).

Follow-up Analyses

Generally speaking, researchers interested in the nature and magnitude of the effects of experimental treatments/conditions on particular dependent variables typically conduct follow-up analyses that may include factorial ANOVAs with subsequent planned and post hoc comparisons. An in-depth treatment of these follow-up analyses and the associated statistical and conceptual issues are beyond the scope of this entry, but the flow chart in Figure 3 illustrates the types of tests and procedures a researcher may utilize to better examine group differences (Bray & Maxwell, 1982; Enders, 2003; Hair, Black, Babin, Anderson, & Tatham, 2006).

Effect Size Estimates

In univariate ANOVA models, a common estimate for the effect size estimate is the ratio of between-group variation, σ_{μ} , to within-group variation, σ , in the population, which is typically denoted by f :

$$f = \frac{\sigma_{\mu}}{\sigma}$$

The multivariate analogue for MANOVA is more complicated to compute and its formula depends on the test statistic that is used. A priori power computations of required sample sizes for studies further depend on the computational algorithm that is used to simultaneously solve the resulting system of equations. Nowadays, freeware programs like GPower3 can perform such computations efficiently in user-friendly environments (Faul, Erdfelder, Lang, & Buchner, 2007; see specifically tables 4 and 5).

Conclusion

MANOVA is an analytic technique that is well suited to investigating a number of applied linguistic research questions. Key constructs of interest such as sociolinguistic competency, lexical richness of discourse, or language comprehension that are psychologically complex typically are best captured using multiple related measures. Furthermore, studies that use

Figure 3 Flowchart illustrating possible analytic paths following a significant MANOVA result

multiple follow-up tests over time are not uncommon. One of the oft-cited advantages of MANOVA is that it allows greater control over the experiment-wise Type I error rate compared to a series of univariate ANOVAs. However, in practice these analyses are often done anyway as “protected F -tests” upon a statistically significant global test result for the MANOVA. Such a two-step approach to analyzing multivariate variance and covariance has statistical limitations (Bray & Maxwell, 1982; Enders, 2003). Therefore, it is perhaps more advantageous to remember a unique advantage of MANOVA over and above univariate ANOVAs, namely that it offers greater statistical efficiency for testing multivariate hypothesis in the form of a specific linear relationship between two or more correlated dependent variables as illustrated above in Figure 2 (Huberty & Morris, 1989). Finally, similar to univariate analyses of covariance (ANCOVA), the inclusion of continuous covariates for improving the power of the test for group differences is also possible within the multivariate general linear modeling framework within which MANOVA is embedded.

Comparing Groups With Multiple Independent Variables

SHAUNA J. SWEET AND ANDRÉ A. RUPP

Factorial analysis of variance (ANOVA) is a specific form of the general linear model in which variation in a single continuous outcome measure of interest, Y , is expressed as a function of the overall and combined effects of two or more categorical independent variables or factors that represent different treatments, conditions, or characteristics. For example, we may be interested in how the average second language reading comprehension scores of students differ across groups created jointly by students' gender and the passage content (Brantmeier, 2003). Or we may wish to examine how the average vocabulary acquisition scores of university students differs across students with different levels of initial language proficiency, sets of target words with different features, and categories of use for target words for academic lectures (Vidal, 2003).

Incorporating multiple factors into a single modeling framework such as factorial ANOVA has two basic advantages. First, the approach is generally more powerful for detecting effects of interest than conducting multiple one-way ANOVAs. Second, it permits testing of interaction effects among predictor variables, which are often of substantive and not just statistical interest (Patterson & Bailey, 1978; Brantmeier, 2004). In reviews of applied linguistics research in both professional journal articles and domain-specific methodology textbooks, ANOVA is consistently referenced as one of the most popular statistical methodologies for making group comparisons on multiple independent variables (Brown, 2004; Henning, 1986; Lazarton, 2002; Brantmeier, 2004).

We begin our discussion of factorial ANOVA by describing three forms of the statistical model, the corresponding statistical null hypotheses, and test statistics; we then describe model assumptions and robustness to violation of those assumptions, and consider testing for unbalanced designs. We then discuss effect sizes and appropriate follow-up tests for specific group comparisons, and conclude with a brief description of factorial ANOVA models for alternative experimental designs.

The Statistical Model

Factorial ANOVA models are a special case of the general linear model and specifically an extension of the one-way ANOVA model. Instead of including one categorical predictor variable in the model, they simply have two, three, or more categorical predictor variables in the model.

In order to illustrate the general structure of a factorial ANOVA model, one has to distinguish between models that contain fixed effects only, models that contain random effects only, and models that contain mixed effects. Technically speaking, hypothesis tests for fixed effects are concerned only with differences in population means for the levels of the factors that were actually included in the study, whereas hypothesis tests for random effects are concerned with the variation among population means for all possible levels of the factors, of which the selected levels in any given study are viewed as a random subset.

2 COMPARING GROUPS WITH MULTIPLE INDEPENDENT VARIABLES

Random effects can be quite common in applied linguistics research, especially when effects of interventions involving students in different classrooms and different schools are investigated. One is often not interested in the particular types of teachers, students, and schools that are included in a study, but rather whether there are mean differences on the outcomes of interest across all teachers, students, and schools more generally. In this sense, random effects often come from sampling designs that lead to hierarchical data structures (e.g., students nested within classrooms or teachers, which are nested within schools).

To formalize these ideas, we juxtapose three factorial ANOVA models with two categorical predictor variables each, which leads to three distinct formulations of two-way ANOVA models. The models that we distinguish are (a) the fixed-effects model, (b) the random-effects model, and (c) the mixed-effects model. Using what is known as the treatment-effects notation, the three models can be written as follows (Lomax & Surman, 2007):

Fixed-effects model (A and B fixed)	$Y_{ijk} = \mu + \alpha_j + \beta_k + (\alpha\beta)_{jk} + \varepsilon_{ijk}$
Random-effects model (A and B random)	$Y_{ijk} = \mu + a_j + b_k + (ab)_{jk} + \varepsilon_{ijk}$
Mixed-effects model (A random, B fixed)	$Y_{ijk} = \mu + a_j + \beta_k + (a\beta)_{jk} + \varepsilon_{ijk}$
Mixed-effects model (A fixed, B random)	$Y_{ijk} = \mu + \alpha_j + b_k + (\alpha b)_{jk} + \varepsilon_{ijk}$

where μ is the overall or grand mean of Y in the population, α_j is the fixed treatment effect for level $j = 1, \dots, J$ of factor A, a_j is the random treatment effect for level $j = 1, \dots, J$ of factor A, β_k is the fixed treatment effect for level $k = 1, \dots, K$ of factor B, b_k is the random treatment effect for level $k = 1, \dots, K$ of factor B, and the interaction effects are defined analogously. ε_{ijk} denotes an individual-level error term, which is the difference between the individual and group-specific mean scores; they are assumed to be normally distributed with a mean of zero and a constant variance. Note that a simple treatment effect is simply the difference between the grand mean and a group-specific mean in the population, which are estimated by the respective sample means; for example, $\alpha_j = \mu - \mu_j$ is the treatment effect for factor level j of factor A.

The Statistical Null Hypotheses

In a basic one-way ANOVA model, the null hypothesis is that the population mean of Y is equal across k groups, which are represented by the levels of the single categorical predictor variable; the alternative hypothesis is that the population mean of at least one group is different from the mean of the other groups:

$$\begin{aligned} H_0 : \mu_1 &= \mu_2 = \dots = \mu_k \\ H_a : &\text{at least two } \mu_i \text{ differ} \end{aligned}$$

For example, we might hypothesize that on average students will perform equally well on a reading comprehension test regardless of class size; the alternative hypothesis is that the average scores of students in small, medium, and large classrooms will be significantly different from one another.

In factorial ANOVA models there are several hypotheses, one for each of the effect terms that is included in the model. In the case of a two-way ANOVA model, there are two main-effect tests for factor A and factor B, respectively, and, if it is included in the model, an interaction-effect test for both factors jointly. Extending our above example, we might be interested in how male and female students (factor A) perform in classrooms of different sizes (factor B). Factorial ANOVA could then be used to investigate (a) if male or

Table 1 Hypotheses for two-way ANOVA model

	<i>Main effect A</i>	<i>Main effect B</i>	<i>Interaction effect AB</i>
Fixed-effects model (A and B fixed)	$H_o : \alpha_1 = \alpha_2 = \dots = \alpha_j = 0$ $H_a : \text{at least one } \alpha_j \neq 0$	$H_o : \beta_1 = \beta_2 = \dots = \beta_k = 0$ $H_a : \text{at least one } \beta_k \neq 0$	$H_o : (\alpha\beta)_1 = \dots = (\alpha\beta)_{JK} = 0$ $H_a : \text{at least one } (\alpha\beta)_{jk} \neq 0$
Random-effects model (A and B random)	$H_o : \sigma_a^2 = 0$ $H_a : \sigma_a^2 > 0$	$H_o : \sigma_b^2 = 0$ $H_a : \sigma_b^2 > 0$	$H_o : \sigma_{ab}^2 = 0$ $H_a : \sigma_{ab}^2 > 0$
Mixed-effects model (A random, B fixed)	$H_o : \sigma_a^2 = 0$ $H_a : \sigma_a^2 > 0$	$H_o : \beta_1 = \beta_2 = \dots = \beta_K = 0$ $H_a : \text{at least one } \beta_k \neq 0$	$H_o : \sigma_{a\beta}^2 = 0$ $H_a : \sigma_{a\beta}^2 > 0$
Mixed-effects model (A fixed, B random)	$H_o : \alpha_1 = \alpha_2 = \dots = \alpha_j = 0$ $H_a : \text{at least one } \alpha_j \neq 0$	$H_o : \sigma_b^2 = 0$ $H_a : \sigma_b^2 > 0$	$H_o : \sigma_{ab}^2 = 0$ $H_a : \sigma_{ab}^2 > 0$

4 COMPARING GROUPS WITH MULTIPLE INDEPENDENT VARIABLES

female students perform better on average (a main-effect test for factor A), (b) whether or not class size has an effect on students' reading comprehension (a main-effect test for factor B), and (c) whether or not class size has a differential effect on the performance of male and female students with regard to average reading comprehension ability (an interaction-effect test for factors A and B jointly). Essentially, the statistical significance of interaction effect means that individual cell means need to be compared, which makes interpretations more complex compared to the case of nonsignificant interaction effects when the means for the levels of factors A and B can be compared separately (i.e., across all levels of the other factor).

Depending on the nature of the effects, the hypotheses differ and have the forms shown in Table 1 (Patterson & Bailey, 1978; Iversen & Norpoth, 1987; Lomax & Surman, 2007). That is, hypotheses for fixed effects are formulated in terms of the specific factor levels included in the study, while hypotheses for random effects are formulated in terms of variances of means across all possible levels.

Experiments investigating three or more factors may also be analyzed using three, four, or n -way ANOVA models. These higher-level ANOVA models are conceptually similar to the two-way models illustrated in Table 1, but analysis and interpretation of the results are more complex due to the larger number of factors involved.

Test Statistics

In one-way ANOVA models, the global or omnibus test statistic is based on an F -distribution and has the following form

$$F = \frac{MS_A}{MS_E} \sim F_{J-1, K(n-1)}$$

which represents the ratio of the mean square for the effect A (i.e., the average variation of scores around their respective group means) to the mean square for the errors (i.e., the average variation of the error terms within each group). As a result of the structure of hypotheses in factorial ANOVA models the test statistics for the different effects change depending on whether the effects are fixed or random; Table 2 shows the resulting F -statistics.

As Table 2 shows, the denominator of tests for main effects for fixed factors becomes the mean square for interaction when the other factor is random while main effects of random factors as well as interaction effects are always tested using the mean square for error in the denominator. Generally speaking, the theory of expected mean squares can be used to determine what the appropriate test statistics should look like. Textbooks on factorial ANOVA models should be consulted whenever at least one effect is random because not all software programs compute the correct test statistics (see Lomax & Surman, 2007).

Model Assumptions and Robustness to Violations of Assumptions

Each factorial ANOVA model comes with a basic set of assumptions, which are required for the sampling distributions of the test statistics to be accurate and, thus, for the p -values and confidence intervals to be trustworthy. These are that the errors are normally distributed within each group with constant variance across groups (i.e., $\epsilon_{ijk} \sim \text{Normal}(0, \sigma^2)$), that the observations are independent within and across each group, and, in the case of random effects, that the factor levels are sampled randomly from a normal distribution with factor-specific variance also (Lomax & Surman, 2007).

Table 2 Test statistics for two-way ANOVA models

	<i>Main effect A</i>	<i>Main effect B</i>	<i>Interaction effect AB</i>
Fixed-effects model (A and B fixed)	$F = \frac{MS_A}{MS_E} \sim F_{J-1, JK(n-1)}$	$F = \frac{MS_B}{MS_E} \sim F_{K-1, JK(n-1)}$	$F = \frac{MS_{AB}}{MS_E} \sim F_{(J-1)(K-1), JK(n-1)}$
Random-effects model (A and B random)	$F = \frac{MS_A}{MS_{AB}} \sim F_{J-1, (J-1)(K-1)}$	$F = \frac{MS_B}{MS_{AB}} \sim F_{K-1, (J-1)(K-1)}$	$F = \frac{MS_{AB}}{MS_E} \sim F_{(J-1)(K-1), JK(n-1)}$
Mixed-effects model (A random, B fixed)	$F = \frac{MS_A}{MS_E} \sim F_{J-1, JK(n-1)}$	$F = \frac{MS_B}{MS_{AB}} \sim F_{K-1, (J-1)(K-1)}$	$F = \frac{MS_{AB}}{MS_E} \sim F_{(J-1)(K-1), JK(n-1)}$
Mixed-effects model (A fixed, B random)	$F = \frac{MS_A}{MS_{AB}} \sim F_{J-1, (J-1)(K-1)}$	$F = \frac{MS_B}{MS_E} \sim F_{K-1, JK(n-1)}$	$F = \frac{MS_{AB}}{MS_E} \sim F_{(J-1)(K-1), JK(n-1)}$

Dependencies between observations that are not explicitly modeled affect the standard errors for model parameters (i.e., the group mean estimates) and thus the accuracy of inferences about model effects. The *F*-test is robust to moderate violations of non-normality but it is sensitive to extreme observations and to heterogeneity of error variance across groups. Unequal error variances across groups introduce bias into the mean square for error, thereby increasing the likelihood of Type I and possibly also Type II errors. As with other statistical models that do not involve latent variables, it is additionally assumed that all variables are measured without error.

One additional assumption of factorial ANOVA is that the factors included in the model are independent of one another. The correlation between predictor variables is generally known as multicollinearity or nonorthogonality and can be controlled by use the design structure that is used, within reasonable practical constraints (Iversen & Norpoth, 1987; Shaw & Mitchell-Olds, 1993; Lomax & Surman, 2007). Correlations between independent variables are not an issue in true experimental designs with a balanced structure (i.e., equal sample size in each group) where the assignment of experimental units (e.g., persons) is randomized. However, unbalanced designs lead to nonorthogonality. They are common in quasi-experimental or observational studies where the observed grouping structure is pre-existing, and naturally occurring groups are of different sizes. This situation is quite common in applied linguistics research; different instructional techniques that are of interest may be employed in classrooms of different sizes, or language learners' initial language proficiency (high, medium, low) is included in the model but the distribution of language learners' proficiency at the beginning of an instructional program is heavily skewed. Even with random assignment within quasi-experimental designs, however, unbalanced data structures can result from attrition or nonresponse. As with other general linear models, correlations between the independent variables can negatively impact the precision and power of the test statistics. The *F*-test is less robust to violations of the normality and homogeneity of variance assumptions when group sizes are unequal and small group sizes generally decrease the robustness of the test (Lattin, Carroll, & Green, 2002; Lomax & Surman, 2007).

Testing in Unbalanced Designs

When group sizes are unequal, it is not possible to disentangle all the separate effects of each of the factors in the model without adjusting the statistical testing procedure because it is not possible to uniquely partition the associated sums of squares for the effects that are needed for the *F*-tests. The solution to this problem is to rely on sequential, partially sequential, or regression approaches. This changes the computation of the resulting sums of squares, which are then labeled Type I, Type II, and Type III sums of squares, respectively, in most statistical software programs.

Table 3 Approaches to hypothesis testing with unbalanced designs

	<i>SS</i>	<i>Main effect (1)</i>	<i>Main effect (2)</i>	<i>Interaction</i>
Sequential/Hierarchical	Type I	$\alpha \mid \mu$	$\beta \mid \mu, \alpha$	$\alpha\beta \mid \mu, \alpha, \beta$
Partially sequential/ Partially hierarchical	Type II	$\alpha \mid \mu, \beta$	$\beta \mid \mu, \alpha$	$\alpha\beta \mid \mu, \alpha, \beta$
Regression	Type III	$\alpha \mid \mu, \beta, \alpha\beta$	$\beta \mid \mu, \alpha, \alpha\beta$	$\alpha\beta \mid \mu, \alpha, \beta$

Note. The “|” notation indicates that the sum of squares for a specific effect is calculated with other effects already included in the model (i.e., “conditional on” other effects).

Each of these approaches uses a slightly different set of rules to adjust each of the main and interaction effects for other factors in the model. The sequential approach adjusts each effect test by accounting for (i.e., conditioning on) effects already in the model; the partially sequential approach adjusts each effect test for other effects at the same level of complexity but not high-order interaction effects; and the regression approach calculates the effect of each factor adjusting for all other factors always included in the model.

With a balanced design all of these approaches yield the same result, but otherwise the three approaches often lead to different conclusions about the hypotheses (Lomax & Surman, 2007). The sequential or hierarchical approach depends heavily on the order in which variables are entered into the model; the partially sequential approach is only reasonable if higher-order interactions are assumed to be zero, and any significant high-order effects are consequently difficult to interpret. Again, it is helpful in practice to refer to basic textbooks on general linear models for specific advice regarding testing procedures.

Effect Sizes

The statistical significance of an F -test does not provide any information on the magnitude of a particular effect and may largely be an artifact of the available sample size. To overcome this limitation, confidence intervals are used as inferential analogues to hypothesis tests, and effect sizes are used as complementary descriptive statistics.

Four measures of effect size are commonly reported in conjunction with factorial ANOVA analyses: eta-squared (η^2), partial eta-squared (partial η^2), omega-squared (ω^2), and Cohen's f (Faul, Erdfelder, Lang, & Buchner, 2007; Lomax & Surman, 2007). Each of these effect-size measures describes the proportion of variance in the dependent variable that is explained by a factor (or combination of factors) in the model using slightly different pieces of information (Pierce, Block, & Aguinis, 2004; Lomax & Surman, 2007). Statistical and discipline-specific resources typically provide rough benchmarks for classifying effect sizes as small, medium, and large but it is the particular study context and study-related research context that should inform the eventual interpretation of the size of effects.

As the ratio of the sum of squares of the effect of interest to the total model sum of squares, η^2 is easy to calculate but it does not account for variation due to error, tending to overestimate the variance attributable to a treatment, and is biased for small samples. Partial η^2 is the ratio of the treatment sum of squares to the sum of the treatment and error sums of squares, and is less biased with small samples because it accounts for variation due to error. Caution should be exercised in reporting classic versus partial η^2 values because partial η^2 generally takes on a larger value than η^2 in factorial ANOVA models and is not additive across effects (Pierce, Block, & Aguinis, 2004). Next, ω^2 is the proportion of variance accounted for by a treatment effect controlling for other treatment effects, and it takes into account both error variance and the structure of the data collection design. It takes on different forms depending on the experimental design, is more difficult to calculate, and less frequently reported than either η^2 or partial η^2 . Importantly, ω^2 is only appropriate for fixed-effect ANOVA models. Finally, Cohen's f is the ratio of the standard deviation of the means to the standard deviation of the errors (i.e., the square root of the ratio of explained to unexplained variation).

Follow-Up Tests

A significant treatment effect may be the consequence of population mean differences between two or more groups. Following a significant F -test, researchers typically perform pairwise comparisons of means, for which a wide variety of procedures exist. The most

common ones are Tukey, Scheffé, and Bonferroni, with the latter procedure being a rather conservative general method for protecting the family-wise or experiment-wise error rate of all such comparisons.

As an alternative to such simple comparisons, researchers also conduct more complex comparisons of multiple group means using contrasts, typically independent or orthogonal contrasts. Orthogonal contrasts are sets of linear combinations of group means so that pairwise comparisons are the simplest cases of contrasts. Statistically, contrasts are characterized by the fact that the weights for the linear combinations of the means sum to zero while the sum of the cross-products of those weights for pairs of coefficients are also zero for orthogonal contrasts. When the categorical predictor variables are measured on ordinal rather than nominal scales, orthogonal contrasts can also be used for trend analyses, which investigate whether there are linear, quadratic, cubic, or higher-order trends in the means along the levels of the ordinal predictor variable. This requires specialized sets of coefficients, which textbooks on general linear models include or programs utilize automatically.

Factorial ANOVA Models for Alternative Designs

As with any general linear model, the strength of the inferences that can be drawn from the inferential tests in the factorial ANOVA model are closely connected to the design structure for data collection. A randomized experimental design with or without blocking supports the strongest form of causal inferences on the basis of an ANOVA model analysis. In practical applications, however, there may be some treatment combinations that are not theoretically significant, not feasible given budget or time constraints, or not ethical (Shadish, Cook, & Campbell, 2002).

With appropriate modifications to the underlying general linear model structure and associated hypothesis tests, factorial ANOVA models can accommodate resulting alternative designs. Such designs include fractional factorial designs, for which many treatment cells are empty; complete and incomplete block designs that include nested factor levels (e.g., certain instructional aids are only available to students in particular classrooms); and repeated-measures designs.

Comparing Two Independent Groups

VEDRAN DRONJIC AND RENA HELMS-PARK

This entry deals with research designs in applied linguistics in which two independent groups of participants are compared. First, the concept of independent groups is defined and contrasted with other designs. Then, a number of essential research and statistical terms related to studies involving two independent groups are elaborated on. Finally, appropriate statistical procedures for analyzing data from such research designs are described, and the reader is pointed to a number of useful sources for further reading.

Independent Groups Research

In experimental research, groups are independent when one group of randomly selected participants is exposed to one condition or treatment and a corresponding randomly selected group to a different condition or treatment (the “independent variable”) and the researcher observes the effect of the independent variable on a dependent variable. This is called independent-measures or between-subjects research. There are experiments without an overt manipulation of an independent variable. Here, groups are determined by participant characteristics, and the characteristic distinguishing one group from the other is called a quasi-independent variable. Alternatively, multiple measurements are taken from a single group, which is referred to as repeated-measures or within-subjects research. However, whenever there is reason to expect that the data may be compromised by test order (e.g., when the posttest in a repeated-measures study closely resembles the pretest), an independent design is preferable. In a third type of situation, separate groups of participants are used, but individual participants in one group are closely matched to identical or near-identical participants in the other group. This is called matched-samples research. The latter two types of study are grouped under the umbrella term “related-samples research” and are considered equivalent for the purposes of statistical analysis (Gravetter & Wallnau, 2007).

In terms of experimental manipulation, researchers working with two independent groups have two main choices. In a comparison group design, both groups receive a treatment. For instance, one might investigate the impact of hypertext glosses versus bolding of text on second language (L2) lexical acquisition. In a control group design, one group (the treatment group) receives a treatment while the other (the control group) does not. Still, it is customary to have the control group perform some kind of language-based task to ensure that any observed differences are attributable to the treatment (Mackey & Gass, 2005). In practice, many applied linguistics studies feature both a control group and a number of treatment groups. With independent groups, the primary method of ensuring that an apparent difference made by an experimental manipulation is not due to extraneous factors is to assign participants to groups randomly (Field, 2005). In fact, true experimentation by definition entails random assignment of participants to groups. This is easier to achieve in some kinds of research (e.g., in most laboratory-based research) than in others (e.g., in research with intact classes). Research in which randomization is not feasible is referred to as quasi-experimental.

Statistical Tests for Comparing Two Independent Groups

When comparing two independent groups, the aim is to ascertain whether the groups are representative of two different populations. Assuming random sampling (to ensure maximum initial comparability), any observed differences should be attributable to the experimental manipulation. In applied linguistics, comparability is commonly confirmed through pretesting, particularly with small samples. As per scientific convention, researchers test the assumption that experimental manipulation will not cause any differences or changes. This is referred to as the null hypothesis (H_0). The opposite is called the experimental (or alternative) hypothesis (H_1). Researchers quantify the likelihood of H_0 not being true on the basis of the observed data by using inferential statistical procedures.

Independent Samples t Test

The most commonly used procedure when comparing two independent groups on a single measurement is the independent samples t test. Essentially, three pieces of information are required for this test: (1) the observed difference between the mean scores obtained from the samples; (2) the expected difference between the means (zero if H_0 is validated); and (3) the estimated standard error of the difference between the sample means. Once a t statistic is computed, researchers consult a statistical table of t values (available in Fisher & Yates, 1974, or most statistics textbooks) to ascertain whether the observed difference between the means is greater than what is expected by chance alone. (SPSS and similar software applications do this automatically.) If this is the case, H_0 is rejected, and it is concluded that the observed difference is due to the experimental manipulation. An important notion here is that of the alpha level, which is defined as the acceptable degree of probability (written as p) that the observed difference is due to chance. The conventional alpha levels vary across disciplines. In applied linguistics, 5% is generally considered acceptable. Therefore, if the p value is less than 0.05, it is said that the observed difference between the groups is statistically significant at the 0.05 level, or, in other words, that the observed differences will be due to chance $\leq 5\%$ of the time when H_0 is true.

The independent samples t test is a parametric test based on the normal distribution. Parametric tests make assumptions about parameters (i.e., characteristics of entire populations as opposed to samples). In order to reach an accurate conclusion, apart from the requirement that the sampling be random (to ensure sample-to-population generalizability), a number of additional assumptions should be met when using such tests: (a) the researcher should be dealing with continuous (interval or ratio) data (i.e., any value within the range should be observable and the difference between, say, 1 and 2 on the scale should be the same as the difference between, say, 5 and 6); (b) the data must come from two independent observations; (c) the data should be normally distributed in both populations; and (d) the variances in both populations should be approximately equal, which is referred to as the homogeneity of variance assumption (Field, 2005; Gravetter & Wallnau, 2007).

With respect to (a), it should be noted that, in practice, researchers frequently treat ordinal data (e.g., data obtained with a Likert scale) as continuous and submit them to parametric tests. If this is done (and there is an unresolved debate about whether it should be done; see Velleman & Wilkinson, 1993; Jamieson, 2004), it should be clearly stated in the research report. If the assumption in (b) is violated, the p value produced might be inaccurate. With regard to (c), while parametric tests tend to be tolerant of violations of normality (Glass, Peckham, & Sanders, 1972), such violations may reduce statistical power (i.e., increase the likelihood of a Type II error, or accepting H_0 when it is false). A number of options exist for dealing with non-normal data (e.g., Wilcox, 2005; McDonough & Trofimovich, 2008), including the use of robust statistics (Larson-Hall & Herrington, 2010). Finally, with regard to (d), there is an alternative way of computing the t statistic if the

homogeneity of variance assumption is violated (see Gravetter & Wallnau, 2007). *SPSS* does this automatically.

When running a *t* test in *SPSS*, it is possible to request a separate test of normality for each group. The Kolmogorov–Smirnov Test is the more commonly used of the two tests performed by *SPSS*. In addition, *SPSS* will automatically test the data for homogeneity of variance using Levene’s Test for Equality of Variances. Nonsignificance on the Kolmogorov–Smirnov Test implies that the data are probably normally distributed and on Levene’s Test that the homogeneity of variance assumption has been met.

For presenting the results of a *t* test, see Gravetter and Wallnau (2007). Norris and Ortega (2000), among others, have pointed out that the reporting of effect sizes should become standard practice in applied linguistics. As *SPSS* does not compute effect size for *t* tests, this is done manually and is a straightforward matter (see, e.g., Rosnow & Rosenthal, 1988; Cohen, 1992). Effect size is usually reported as Cohen’s *d* (indicating the mean difference in terms of standard deviations) or as the percentage of variance accounted for (or r^2). Cohen (1988) has suggested guidelines for interpreting effect size using these statistics.

Nonparametric Tests for Comparing Two Independent Groups

When comparing two independent groups, there are occasions when independent samples *t* tests are not advisable, namely, when the above assumptions are not met. In such situations, there are two alternative inferential statistical techniques, the chi-square test for independence and Mann–Whitney *U*, both belonging to a family of procedures called nonparametric tests. While these do have less stringent requirements than parametric tests, they also have less statistical power and therefore might not always detect a genuine effect (cf. Type II error above). When the assumptions for parametric tests are violated, researchers may decide to perform both parametric and nonparametric tests and report whether the results of the tests correspond. It is not uncommon for researchers to report only the results of the parametric test if the results of the two tests agree.

Mann–Whitney *U* is the nonparametric alternative to the independent samples *t* test for data which can be meaningfully ranked. Here, the groups’ scores are combined and rank ordered. A subsequent procedure establishes whether the two sets of scores cluster at opposite ends of the distribution or are mixed relatively evenly. In short, this test reflects the level of overlap between the groups’ scores. The Mann–Whitney *U* test assumes that the data come from independent observations, that the dependent variable is continuous, and that scores are disparate enough to make ranking meaningful, that is, that there are not a large number of identical scores (Gravetter & Wallnau, 2007). For more on this test, including the reporting of results, see Gravetter and Wallnau (2007). For example, in a study of the acquisition of English causatives by Hindi and Vietnamese speakers, Helms-Park (2001) used multiple-choice, grammaticality judgment, and production tests that were scored on a scale of 0 to 4. A Mann–Whitney *U* test was used because many of the distributions were not normal and had unequal variances, rendering the *t* test unsuitable.

Note that multiple comparisons between two independent groups are commonly required (in fact, due to increasing sophistication in design, studies comparing only two means are rare in present-day applied linguistics). In such situations, *t* tests (or their nonparametric counterparts) are inappropriate since running multiple tests on the same data increases the likelihood of Type I error (i.e., finding significant differences between groups when there are in fact none); this is known as familywise or experimentwise inflation of the error rate. For instance, Costa, Caramazza, and Sebastián-Gallés (2000) compared Spanish monolinguals and Catalan–Spanish bilinguals on speed of naming pictures in Spanish. In one of the tasks both the first language of the participants and cognate status of the picture names were manipulated. Thus, apart from contrasting monolinguals and bilinguals, the researchers also compared naming speeds for cognate and noncognate picture names. In

4 COMPARING TWO INDEPENDENT GROUPS

Dronjic and Helms-Park (2009), two groups of participants completed the same vocabulary test but with different instructions. Besides an overall score, subscores were obtained for both paradigmatic relations and collocations. Dronjic and Helms-Park were indeed able to use an independent samples *t* test to compare the overall test scores. However, to avoid familywise inflation of the error rate, both sets of researchers used a repeated-measures analysis of variance (ANOVA) for their multiple comparisons. Note that if multiple *t* tests must be performed, a reduction of the alpha level is necessary (see Gravetter & Wallnau, 2007).

Comparing Two Related Samples

XIANGYING JIANG

Introduction

The related samples design, which compares the means of two groups that are related, is widely used in applied linguistics research. For example, let us say we want to know if the English reading performance of a group of English as a second language (ESL) students has improved after an instructional treatment during a one-semester English reading class. To make this determination, we could randomly select students from an ESL student population and enroll them in a one-semester English reading class or, more likely, we would use an intact class. A pretest and posttest would be administered at the beginning and the end of the semester, respectively. This is a typical pre- and post-experimental design (for the randomly assigned group, or quasi-experimental design for the intact group), in which each pair of responses is related because it comes from the same individual. Another design that would result in two related samples is the so-called matched pairs design. In this design, each pair of responses comes not from the same individual, but from two individuals that are somehow matched (e.g., by age, intelligence, or prior performance). Two statistical methods, the paired samples *t* test and the Wilcoxon signed-rank test, are designed to compare the two related samples. This entry explains both statistical methods, covering the following topics: the logic of the test, assumptions, example data, running a computer application, and interpreting the results, including effect size. The entry concludes by discussing the advantages and disadvantages of each method.

Paired Samples *T* Test

Logic of the Test

The paired samples *t* test is designed to determine whether differences exist between the means of two related samples. (This test is also referred to as a dependent *t* test and a matched pairs *t* test.) It is important to understand that testing whether the two sample means are equal is the same as testing whether the mean of the difference scores between the two samples is zero. Thus, the paired samples *t* test is essentially an extension of the one-sample *t* test. That is, what the paired samples *t* test does is to first transform the two related samples into one single sample of difference scores by subtracting one sample from the other and then evaluate the mean of the difference scores against zero (Howell, 2002). Like the two independent samples *t* test, the paired samples *t* test requires that the two measures be the same or in parallel forms (e.g., reading scores 0–100 in both samples 1 and 2). The measures must be at the interval level of measurement, at least.

A null hypothesis that says the mean difference equals zero is tested. The null hypothesis would be rejected if the probability obtained were less than or equal to a preselected significance level, such as $\alpha = .05$. On the other hand, we would fail to reject the null hypothesis if the probability obtained were greater than the preselected significance level $\alpha = .05$.

2 COMPARING TWO RELATED SAMPLES

Table 1 Hypothetical data on reading comprehension from a group of ESL students

<i>Student</i>	<i>Pretest</i>	<i>Posttest</i>	<i>Difference</i> $X_d = \text{Post} - \text{Pre}$
1	85	94	9
2	56	62	6
3	92	85	-7
4	84	86	2
5	65	72	7
6	90	95	5
7	56	66	10
8	70	70	0
9	76	79	3
10	83	87	4
11	80	79	-1
12	52	60	8
		Sum	46
		Average	3.83

Assumptions of the Test

There are three assumptions for the paired samples t test: (1) Observations for each pair should be made under the same conditions; (2) the mean differences should be normally distributed; and (3) variances of each variable can be equal or unequal (SPSS Inc., 2007). For example, we must make sure that the pretest and the posttest in the above example take place under identical conditions to satisfy assumption 1. One instance of incomparability would be if students were given cloze questions in the pretest but multiple-choice questions in the posttest. To satisfy assumption 2, the population of difference scores must be normally distributed. You may assess normality by using a histogram, stem-and-leaf plot, or Q-Q plot. But the normality assumption is not a strong one. Sometimes, a reasonable violation of the assumption is well tolerated as long as the sample size is large. Assumption 3 is not much of a concern since it states that the population variances can be either equal or unequal.

Example Data

Table 1 presents some hypothetical pre- and posttest data on reading comprehension from a group of ESL students. Subject number is in column 1, pretest scores in column 2, posttest scores in column 3, and difference scores in column 4 (column 3's posttest - column 2's pretest). A positive difference score shows that the student did better in the posttest than in the pretest, and vice versa. The last row of column 4 displays the mean difference of 3.83, which is to be statistically evaluated against zero.

Running a Paired Samples T Test

To run the paired samples t test in SPSS (currently renamed PASW), we first enter the data into a SPSS datasheet as shown in Figure 1.

Then, we click Analysis > Compare Means > Paired-Samples T Test to access the procedure. The remaining steps are self-explanatory and are illustrated in Figure 2.

The image shows the SPSS Data View window for a file named '*Assessment of Reading Comprehension.sav'. The window displays a table with 14 rows and 5 columns. The columns are labeled 'Subject', 'Pretest', 'Posttest', and 'var'. The 'Subject' column contains numbers 1 through 14. The 'Pretest' and 'Posttest' columns contain numerical scores. The 'var' column is empty. The window also shows a menu bar with options like File, Edit, View, Data, Transform, Analyze, Graphs, Utilities, Add-on, Window, and Help. A toolbar with various icons is visible below the menu bar. The status bar at the bottom indicates 'PASW Statistics Processor is ready'.

	Subject	Pretest	Posttest	var
1	1	85.00	94.00	
2	2	56.00	62.00	
3	3	92.00	85.00	
4	4	84.00	86.00	
5	5	65.00	72.00	
6	6	90.00	95.00	
7	7	56.00	66.00	
8	8	70.00	70.00	
9	9	76.00	79.00	
10	10	83.00	87.00	
11	11	80.00	79.00	
12	12	52.00	60.00	
13

Figure 3 SPSS output from the paired samples t test

Interpreting the Results

SPSS displays the results in three boxes (Figure 3). The first box displays descriptive statistics for each variable. In the second box, the correlation coefficient ($r = .942$) shows strong correlation between the two samples, which is expected. The third box displays the output of the paired samples t test. The first three columns display the descriptive statistics for the difference scores. Notice that the mean difference is positive (as we saw in Table 1). Column 7 shows that t equals 2.74 and the last column shows that the p -value (2-tailed) of this t equals .019. Since the p -value is less than the critical value $\alpha = .05$, we reject the null hypothesis and conclude that the two samples are significantly different. Since the mean difference is positive, we can understand that students did significantly better, statistically, in the posttest than in the pretest.

Effect Size

To estimate the magnitude of a significant effect (i.e., the effect size), one of two approaches is often used for a paired samples t test: the standardized mean difference (Cohen's d) or the strength of association (eta squared). Although designed for two independent samples, Cohen's d is found to be also appropriate for calculating the effect size for two related samples (Dunlop, Cortina, Vaslow, & Burke, 1996). SPSS does not provide Cohen's d in the paired samples t test procedure. To obtain this statistic, you can access one of the online Cohen's d calculators (e.g., <http://www.danielsoper.com/statcalc/calc48.aspx>). In our example, the calculator returns a $d = 0.30$, which indicates that the posttest score was about

$1/3$ a standard deviation greater than the pretest score, a relatively small effect size. To compute eta squared, square the observed t value and divide that by the observed t squared + df (Hatch & Lazaraton, 1991). In our example, the value is .41, meaning that the instructional treatment accounted for 41% of the variance between the posttest score and the pretest score.

Wilcoxon Signed-Rank Test

Logic of the Test

As discussed previously, the paired samples t test requires that the population of difference scores is normally distributed. If it appears that this assumption is violated, you may consider using the Wilcoxon signed-rank test, which is a distribution-free procedure. The logic of the Wilcoxon test is as follows. The test first transforms the numerical difference scores into a set of signed ranks based on the magnitude of these difference scores. Then statistical inference is made on whether or not the mean rank equals zero (Wilcoxon, 1945).

The null hypothesis is that there is no difference between the pretest and the posttest. Being a signed-rank procedure, the Wilcoxon's test essentially tests the null hypothesis that the mean rank equals zero. We would reject the null hypothesis and conclude that there is a significant difference between the pretest and the posttest if the p -value of the observed Z statistic were less than $\alpha = .05$. On the other hand, we would fail to reject the hypothesis and conclude that there was no significant difference between the pretest and the posttest if the p -value were greater than $\alpha = .05$.

Assumptions of the Test

The assumption for the Wilcoxon signed-rank test is that the population distribution of difference is symmetric. The different data do not need to have a normal distribution (SPSS Inc., 2007). But the data must be continuous, that is, at least at the ordinal level of measurement.

Example Data

We further examine this method by revisiting the pretest and posttest data in Table 1. We begin by rearranging the set of difference scores in order of increasing absolute value, which yields: 0, -1, 2, 3, 4, 5, 6, 7, -7, 8, 9, 10. Then, we discard the difference of zero, replace the above numbers with numbers 1 through 11, and keep algebraic signs. These steps yield these ranks: -1, 2, 3, 4, 5, 6, 7.5, -7.5, 9, 10, 11. Notice that the two values (7.5 and -7.5) are the average of the adjacent tied ranks 7 and 8 (i.e., 7 and |-7|). The subsequent Wilcoxon test is performed on these ranks instead of on the original numerical values.

Running the Wilcoxon Test

To run the Wilcoxon test in SPSS, we first enter the data in an SPSS datasheet as shown in Figure 1. Then we access the procedure by clicking Go to Analysis > Non-Parametric Test > 2 Related Samples. The remaining steps are self-explanatory and are illustrated in Figure 4.

Interpreting the Results

As shown in Figure 5, the first box of the output displays the descriptive statistics for each variable. The second box shows the rank statistics. In the first column of this box, SPSS

Figure 4 Two-related-samples tests dialogue box in SPSS

output shows that there are 12 ranks in total, 2 of which are negative (i.e., -1 , -7.5), 9 are positive (i.e., 2, 3, 4, 5, 6, 7.5, 9, 10, 11), and 1 is a tie (where $\text{posttest} - \text{pretest} = 0$). The last column shows the sum of negative ranks (i.e., $1 + 7.5 = 8.5$; the negative signs are ignored) and the sum of the positive ranks ($2 + 3 + 4 + 5 + 6 + 7.5 + 9 + 10 + 11 = 57.5$), respectively. The column to its left shows the mean negative ranks ($8.5/2 = 4.25$) and mean positive ranks ($57.5/9 = 6.39$). The p -value (2-tailed) of the z score tells whether or not the two samples are significantly different. SPSS uses the smaller one of the two sums of ranks (i.e., 8.5) to calculate the z score. The z score is found to be -1.79 . Since the 2-tailed probability ($p = 0.029$) is less than the preselected significance level $\alpha = .05$, we may conclude that there is a significant difference between the pretest and posttest. Since the mean of the posttest is greater than the mean of the pretest, we may conclude that the students did significantly better in the posttest than in the pretest.

Effect Size

To compute the strength of association for the Wilcoxon signed-rank test, square the Z test statistic, and divide it by $N-1$ (Hatch & Lazaraton, 1991). In our example, $\eta^2 = .43$.

Advantages and Disadvantages

Finally, we discuss the advantages and disadvantages of the paired samples t test versus the Wilcoxon signed-rank test. The paired samples t test is a parametric test and, as such, requires the assumption of normality. However, as long as the assumption is satisfied, the paired samples t test is more powerful than the Wilcoxon test. That is, the paired samples t test is more likely to detect differences when differences exist. Therefore you should use the paired samples t test as long as the normality assumption is satisfied. Sometimes, even a reasonable violation of the normality assumption is tolerated. In contrast, the Wilcoxon

Descriptive Statistics

	N	Mean	Std. Deviation	Minimum	Maximum
Pretest	12	74.0833	13.98349	52.00	92.00

a. Based on negative ranks.

b. Wilcoxon Signed Ranks Test

Figure 5 SPSS output from the Wilcoxon signed-rank test

test is a nonparametric method and, as such, does not assume normality of distribution. This method is less powerful because it ignores available information by replacing interval or ratio level values with ranks. However, when there is a clear violation of the normality assumption, which occurs often when sample size is small, as often is the case in applied linguistic research, the Wilcoxon test is preferred. The Wilcoxon test is also preferred when there are outliers in the data because rank-based statistics are less sensitive to outliers (Norusis, 2009).

Comparing Two+ Independent Groups

JENIFER LARSON-HALL

A statistical comparison among groups asks the basic question of whether the means of the groups differ widely enough to conclude that the groups come from different populations. Many times in applied linguistics the groups are composed of human participants, and the reasons they could differ are because the groups received different types of experimental treatments or teaching methods, or because the participants differ in fundamental ways such as memory ability or past experiences. One example would be a comparison of how well three groups understood a piece of literature based on different types of analysis: traditional teacher-led discussion, discovery analysis with students doing most of the questioning, and a control group who simply read the text with no analysis at all. Another example would be examining Arabic speaking proficiency looking for evidence that experience with the language in different contexts (naturalistic exposure versus instructed immersion versus non-immersion instruction) was an important factor for proficiency. If a statistical test finds that the groups are significantly different, we may infer that the variable we are looking at (type of teaching method in the first example or learning context in the second) played a role in affecting participants' outcomes, and we can quantify the practical effect of that variable with another statistic called *effect size*.

Logic

A comparison among the means of more than two groups asks whether the variable that is measured (the dependent variable) is affected by another variable of interest to us (the independent variable). If this variable of interest, such as teaching method, preparation time before writing, or type of words being learned (which are all categorical variables) is found to be statistically significant, then this means that the independent variable had some effect on the outcome of the dependent variable.

The question of whether, overall, the independent variable had an effect on the dependent variable is answered in the omnibus test of a one-way ANOVA statistical test (ANOVA stands for ANalysis Of VAriance). The omnibus test is the one that produces an *F* statistic and an associated *p*-value (you can see an example later in this entry in Figure 1). Mathematically, ANOVA tests the ratio of the amount of variation within the groups themselves (do the scores of individuals within the group vary widely or is there only a small range of different scores within one group?) and between the separate groups (what is the difference in scores across the groups?). If the groups are highly different from each other but the variation is small within the group, the *F* statistic will be large (over 2) and the test will be statistically significant. If the groups are highly different from each other but there is also a wide variation within the groups, the *F* ratio will be smaller and the test may not be statistically significant. Obviously, if the groups are not very different from one another it is not likely that the ANOVA *F* statistic will be large.

Even if the omnibus test is statistically significant there is still a further question to ask—which levels of the independent variable are statistically different from one another and how do they differ? For example, in looking at the effects of different types of oral

2 COMPARING TWO+ INDEPENDENT GROUPS

error correction with three different treatment groups, you wouldn't just want to know that overall error correction type made a difference to outcomes (the question the omnibus test answers) but you would also want to know about specific differences between the treatments. Did the two groups which received correction do better than the control group which received no correction? Did the method of explicit correction work better than implicit correction? To answer this question one can perform post hoc tests or planned comparisons. Post hoc tests compare all of the groups to one another one at a time, testing for statistical differences. Planned comparisons are better used when you have a large number of groups but are not interested in every single comparison between groups. Planned comparisons let you choose which groups to compare to one another.

To summarize so far, if you have a dependent variable that is a continuous or interval-level and you have just one independent variable that is categorical or nominal and has two or more levels, you can use a statistical test to investigate whether the mean response differs between levels or groups. If you only have two levels in your independent variable, meaning you only have two mean scores, you should use a *t* test to compare two independent groups. On the other hand, if you have two, three, or more categorical independent variables, you can use factorial ANOVA models.

Assumptions

In conducting your statistical test of comparing two+ independent groups, you will need to decide if you would like to use a parametric, nonparametric, or robust test. If you want a parametric test, you will choose the one-way ANOVA. Parametric tests involve estimating the distribution of scores in a population, using the data sampled from the population. Because of this, parametric statistics involve making assumptions about the shape of the distribution, chiefly that the data are normally distributed and that the variances are equal.

For the assumption of a normal distribution, Larson-Hall (2010) argues that it is virtually impossible to tell whether your data are exactly normally distributed or not if sample sizes are small (under 50 in each group). Therefore, it is judicious to look only for extreme skewness by examining histograms and for outliers by looking at a boxplot. If you have skewness or outliers your data are not normally distributed.

The assumption of equal variances means that all of the groups have similar variance (or the square root of the variance, which is the standard deviation). Examine the numerical standard deviation of the groups compared to the total number of points to decide whether variances are equal. Some statistical programs allow you to test the assumption of equal variances with Levene's test of homogeneity of variances, and this can be one more piece of evidence that group variances are equal or not (the *p*-value for this test should be *over* .05 to conclude that variances are equal).

Nonparametric tests do not assume that distributions are normal (although they do assume that the population distributions are equal, which is similar to the assumption for parametric statistics that variances are equal), and they also do not rely on measures of location such as the mean, which can be skewed by outliers. The nonparametric analogue to the one-way ANOVA is the Kruskal-Wallis test, and the nonparametric analogue to post hoc tests is the Mann-Whitney test. Many authors use nonparametric tests when their data do not satisfy the assumptions of parametric tests, but assume that such tests are not as powerful as parametric tests.

In fact, the power to find out the actual situation (whether groups differ depending on the independent variable) depends on the shape of the data, so that parametric tests may not be as powerful as nonparametric tests when their assumptions are not satisfied (Maxwell & Delaney, 2004). Power is a technical term that is measured on a percentage scale from 0

to 100 and notes the probability of finding a difference between groups when that difference does exist, but it can also be understood in its normal sense of being strong enough to find real differences. Both parametric and nonparametric statistics can be susceptible to considerably lower power if distributions are skewed or have unequal variances (Wilcox, 1998). Howell (2002) notes that when you expect unequal variances (such as in the case when you might be comparing native speakers to non-native speakers and expect much less variance in scores from the native speakers), it is especially important to try to keep group sizes equal.

If either the normality assumption or the equal variances assumption does not hold, you may still proceed with a parametric statistical test. Be aware, however, that you may fail to have the power to find differences which actually exist. Although many statistical users have heard that the ANOVA procedure is relatively robust (in other words, immune) to departures from assumptions, simulation studies with simple statistical tests have shown that they are not (Tukey, 1960; Hampel, 1973). Modern statistics has developed more sophisticated statistical tools that can better deal with departures from assumptions and have higher power, and this collection of tools is labeled robust statistics (for more information about these types of statistics, see Larson-Hall & Herrington, 2010). Wilcox, Keselman, and Kowalchuk (1998) found that a robust method was quite effective at dealing with the situation when three unwanted conditions all held at the same time: group distributions were non-normal, variances were unequal, and group sizes differed.

There are two more assumptions that all data which is analyzed with a comparison of group means must follow. One is that the data are independent, and the other is that the dependent variable is measured as an interval-level variable.

Most statistical practitioners would like some guidelines with respect to sample sizes. Although 30 is sometimes given as a rule of thumb for a minimum size for a study (for 3 groups, that would be 10 minimum in each group), in reality the size you need depends on how strong the effect you are studying is. If you are studying a phenomenon which exists but has a small effect size, you may need over 100 people in each group in order to have enough power to find any differences, but if the effect size is large, 10 in each group would be sufficient. Thus, you should be aware that just because you don't find any differences between groups does not mean they do not exist; in such a case you should look at how much power your statistical test had. If it had strong power (.80 or higher) then you may conclude it is unlikely that there are real differences between your groups. However, if your power is low, then you can only conclude that you would need more participants in order to answer your question (for detailed instructions about calculating power in the R statistical program, see Larson-Hall, 2010).

Example of Parametric Technique

To illustrate the parametric one-way ANOVA data from an unpublished study by Larson-Hall will be used (google "Larson-Hall," "forgotten" and "Routledge" and you'll find the actual data online as an SPSS file). The data examine Japanese users of English. Some of them lived in the US as children, but returned to Japan and essentially lost their English. They are called "Early immersionists." Another group lived in the US as adults, and they are called "Late immersionists." A third group was majoring in English at a university but had never lived abroad. They are the "Non immersionists." The dependent variable is a phonemic discrimination test, where listeners had to identify whether the word they heard began with the English sound [ɪ], [I], or [w]. Essentially, the question was how the age at which the learner began learning the L2 and living in the target-language country might affect the ability to discriminate among these sounds.

4 COMPARING TWO+ INDEPENDENT GROUPS

ANOVA					
Score on the R/L/W listening test					
	Sum of squares	df	Mean square	F	Sig.
Between groups	1481.589	2	740.794	3.527	0.39
Within groups	8611.048	41	210.026		
Total	10092.636	43			

Figure 1 Output for the omnibus test of a one-way ANOVA using SPSS

Omnibus Results

Using any type of statistical software, you will have several different pieces of output for the results of the one-way ANOVA statistical test. You should first look at your descriptive statistics, especially the means and standard deviations of your groups, and get familiar with your data. Always be sure to report your descriptive statistics somewhere in your report; for a one-way ANOVA, effect sizes will be calculated from means and standard deviations, so your reader will need to see these.

The second piece of information you'll want to examine is the omnibus ANOVA results. The output from an SPSS one-way ANOVA is found in Figure 1. You'll need to report the data in the columns for "df," "F" and "Sig." (the other columns give results of the mathematical steps in calculating the F ratio). The "df" column gives the degrees of freedom for both the "Between groups" calculation and the "Within groups" calculation (this is also sometimes called the error df). You'll need to report both of these numbers. The "F" column gives one number, which is the final result of the mathematical calculations of the ANOVA. If it is over 2 it is likely that the associated p -value will be less than .05, indicating a "statistically significant" result. The value in the "Sig." column is the p -value of the omnibus one-way ANOVA test. If it is less than .05, we can reject the null hypothesis that there is no difference among the groups we are testing.

Given the output found in Figure 1 we can say that for this test of phonemic discrimination there is a difference among the three groups. We can report this by saying something like "A one-way ANOVA found a statistical difference among groups, $F_{2,41} = 3.5$, $p = .039$."

Post Hoc Results

Given that the omnibus test is statistically significant, we can then examine the results of post hoc tests comparing the groups two at a time in pairwise comparisons. There are many choices available for the type of post hoc test to use, and they differ in how much they adjust the raw p -value to make up for the fact that you are doing multiple tests (by simply performing many statistical tests you may get a statistically significant result merely by chance). The LSD test will actually not make any adjustment to the alpha level, and Howell (2002) recommends this as the best post hoc test when you have only three groups. If you want to use an adjustment, Bonferroni is more powerful than Tukey when fewer tests are done, but Tukey has more power when more tests are done. You may also choose post hocs which can help adjust for violations of the homogeneity of variance assumptions, including the Games–Howell post hoc (more powerful) and Dunnett's T3 (more conservative). If you use the R statistical program, you could use the LSD to get raw p -values and then use the newer Benjamini and Hochberg False Discovery Rate algorithm to adjust p -values (<http://www.unt.edu/benchmarks/archives/2002/april02/rss.htm>).

Since there were only three groups, the statistical analysis uses LSD post hoc tests, which are seen in Figure 2. Basically, this figure shows the results of three tests. However,

Multiple Comparisons

(I) Status	(J) Status	Mean difference (I-J)	Std. error	Sig.	95% confidence interval	
					Lower bound	Upper bound
Non	Late	-1.467	5.292	.783	-12.15	9.22
	Early	-13.124*	5.385	.019	-24.00	-2.25
Late	Non	1.467	5.292	.783	-9.22	12.15
	Early	-11.657*	5.385	.036	-22.53	-.78
Early	Non	13.124*	5.385	.019	2.25	24.00
	Late	11.657*	5.385	.036	.78	22.53

Figure 2 Results of the LSD post hoc tests from a one-way ANOVA

Note. * The mean difference is significant at the 0.05 level.

the actual number of entries is doubled by reversing the order of the comparison, resulting in six pieces of information. For example, the "Non versus Late" group comparison is given in the first row of output, and the reversed "Late versus Non" group is given in the third row of output.

The second column of Figure 2 shows the mean difference, which is the raw difference in mean scores between the two groups. The last two columns, titled "95% confidence interval," give the range within which, with 95% confidence, the mean difference would fall with repeated testing. One may use the 95% confidence interval (CI) in the same way as the p -value (found in the column "Sig.") to determine statistical significance: if the interval passes through zero, then it is possible that the actual mean difference is zero, and thus there is no difference between groups. However, if the interval does not pass through zero the difference is statistically significant (and the range of the CI gives an idea of how large or small the difference between the two groups could be). The column "Std. error" gives a measure of variance that we do not need to use.

My results show that the comparison between the Non and Late group is not statistically significant ($p = .783$), the comparison between the Non and Early group is statistically significant ($p = .019$), and the comparison between the Late and Early group is also statistically significant ($p = .036$). Report these results in this way: "LSD post hoc tests found statistically significant differences between the Non and Early group ($p = .019$) and the Late and Early group ($p = .036$), but no statistically significant difference between the Non and Late group ($p = .783$)."

Effect Sizes

It is always important to include effect sizes when giving the results of a study. Generally, the effect sizes for the differences between two groups (the post hoc tests) will be more informative than the effect size for the omnibus ANOVA. For this reason, you can use the same method for calculating effect sizes as is used for t tests. Using an online calculator (<http://www.uccs.edu/~faculty/lbecker/>) you can input mean scores and standard deviations to find effect sizes for paired comparisons. Using the Larson-Hall data (Non: mean = 67.7, sd = 13.8; Early: mean = 80.9, sd = 14.3; Late: mean = 69.2, sd = 15.4) the Cohen's d effect size for Non versus Early is $d = .94$, meaning the groups differ by almost an entire standard deviation, which is quite a large difference. For Early versus Late $d = .79$ (also a large difference) and for Non versus Late $d = .1$ (negligible effect size). Effect sizes show how *important* the difference between groups is. Effect sizes don't change based on the

6 COMPARING TWO+ INDEPENDENT GROUPS

group size, while statistical outcomes do. This is why you should also give effect sizes for nonstatistical comparisons as well as statistical ones, because you may find important effects even if the statistics indicate that the comparison is not statistical.

Comparing Two+ Related Samples

FLORIN M. MIHAI

What Are Related Samples?

In a survey of four major applied linguistics journals, more than 40% of the linguistics studies had used a design where the means of more than two samples were compared (Lazaraton, 2005). In many instances, researchers have employed a repeated measures design with the purpose of measuring the same dependent variable across two or more intervals. For example, a linguist might want to measure pronunciation accuracy of students taking an accent reduction course at 1-, 3-, and 6-month intervals after course completion.

Parametric Techniques

In studies where the same set of individuals participates in all of the different treatment conditions, researchers who want to use a parametric test should use repeated measures (RM) ANOVA. There are several possible designs for RM ANOVA, the most frequent ones being one-way and two-way RM.

In a one-way design, we test whether the mean value of a single variable differs significantly among the three or more levels of a set of conditions, also called a factor. For example, a group of researchers wants to test whether reading proficiency in the second language (L2) is affected by noise levels. To do that, they measure reading comprehension at three different noise levels: low, moderate, and high. Each participant experiences each of the noise levels in a random order. Noise is the factor and the reading comprehension score of the participants is the repeated measure.

A two-way design is used in experiments involving more than two sets of conditions. Continuing with the previous example, let us assume that the researchers wanted to include an intervention—giving students training in ignoring noise. Pretests were given before the intervention, under each of the three noise conditions, followed by three posttests (again under each noise condition) given after the intervention. Now we have two factors: noise and time. The reading comprehension score for each condition is the repeated measure. This design would allow the researchers to examine the main effects of time and noise, as well as possible interactions (whether the treatment was effective for the low noise condition, but not for the high noise condition).

RM ANOVA designs are particularly useful in certain data conditions. First, great variation among participants may inflate error variance estimates; using RM on each participant provides a way of controlling for this source of variation and reducing error variance (Stevens, 1996). Second, sometimes a sufficient number of participants is difficult to recruit; these designs are cost-effective because each member is measured under all conditions, and moreover, inferential testing becomes more powerful because the sample size is not divided between conditions or groups.

However, there are some disadvantages when using RM design. Participants may get better (practice effect) or they may get worse (fatigue effect) as the experiment progresses over time. Additionally, the order in which conditions are experienced may affect the

2 COMPARING TWO+ RELATED SAMPLES

performance of the participants. One last disadvantage is that statistical assumptions are seldom met when running an RM ANOVA (Girden, 1992).

With regard to statistical assumptions, like any ANOVA, RM ANOVA assumes the following (Howell, 2006):

1. normal distribution of data,
2. homogeneity of variance, and
3. homogeneity of covariance if the treatment factor has more than two levels.

RM ANOVA is not very sensitive to the violations of assumptions 1 and 2. If assumptions 2 and 3 are met, then we can describe the population of the study as showing a condition called compound symmetry, a desirable condition but more strict than necessary. Assumptions 2 and 3 can be relaxed as long as there is sphericity, which is the assumption of homogeneity of variances and covariances within each level of the within-subjects factor (Field, 1998). A result violating this assumption cannot be trusted because it increases the Type I error rate. A Type I error occurs when researchers conclude that there are differences between a set of conditions (with related samples such as pretest vs. posttest) when in fact there are none. However, other statistics can be used which correct for this violation and these are typically provided in statistical output.

Example

To exemplify the statistical output of a one-way RM ANOVA design, let us examine a hypothetical study related to vocabulary acquisition in an L2. In this study, researchers want to investigate the effect that a new approach in teaching L2 vocabulary has on integrating vocabulary items into L2 students' long-term memory. Baseline data are collected and vocabulary retention is measured at 3, 6, and 9 months after the treatment has been administered. Table 1 shows the raw data for 32 participants.

Figures 1, 2, and 3 display the output generated using SPSS (Statistical Package for the Social Sciences) for the data set listed in Table 1. In Figure 1 we can see that the mean vocabulary score at the time the baseline data were collected is lower than at the other three times. We can also see that the standard deviation across the four times is similar.

Figure 2 displays the results of Mauchly's sphericity test. This test is based on the likelihood ratio criterion and involves a scaled comparison between the determinant and the trace of the sample covariance matrix (Anderson, 1958). The significance level in the example is less than .05 so there are significant differences between the variance of differences. Therefore, sphericity cannot be assumed. Corrections for violations of sphericity include the Greenhouse-Geisser, the Huynh-Feldt, and the Lower-bound corrections. If epsilon (Figure 2) is less than .75, we should use the Greenhouse-Geisser correction, whereas for cases when epsilon is larger than .75, we should use the Huynh-Feldt correction.

Figure 3 SPSS output from RM ANOVA for Table 1 data set

Based on the results from the sphericity test, the researchers used Greenhouse-Geisser correction and reported a significant F statistic of 311.81, indicating that a statistically significant difference was found among the four times the vocabulary data were collected. The practical significance for this statistical finding can be estimated by effect size. The effect size (partial eta squared) can be obtained by calculating the percentage of variance that is explained by the differences in treatment. Specifically, the sum of squares for Factor1 (the error accounted for by time of data collection, 11,083.125) is divided by the total variance (11,083.125 + 1101.875, or 12,185). This results in .91. For the data set in Table 1, then, the partial eta squared or η^2 is .91 or 91%, which means that 91% of the variability in the data is accounted for by the differences between treatments and is interpreted as a large effect size and one that is practically significant.

When reporting data, the following information should be included: the descriptive statistics, the type of ANOVA used (one-way RM, in this example), F-values (the F column in Figure 3), degrees of freedom (between, 1.56, and error, 48.46, found in the df columns in Figure 3), *p* value (.000, found in the Sig. column in Figure 3), and whether or not the differences were significant. In the case of Table 1 data, the results using Greenhouse-Geisser correction are significant, because the *p* value as reported by SPSS is less than .0005 (rounded to .000 in the figure), making the rejection of the null hypothesis very likely. Figure 3 contains error values where error is defined as the amount of unexplained variation across the conditions of the repeated measure variable. Because the statistical analysis figures the error term in its calculations (F is the variance between treatments divided by variance due to chance or error), we do not report those values.

Because a significant difference was found among the four times that the vocabulary data were collected, the researchers may decide to run subsequent analyses, referred to as *post hoc* analyses. These are a series of *t* tests comparing the means of two time periods. For example, baseline would be compared to 3 months, then to 6 months, and then to 9 months; then 3 months would be compared to baseline, 6 months, and 9 months; and so forth. The purpose of these multiple *t* tests is to pinpoint which group means are significantly different from one another. Typically, adjustments are made, such as the Bonferroni adjustments, to address Type I error of multiple comparisons.

Nonparametric Techniques

The Friedman analysis of variance by ranks or the Friedman test is a nonparametric alternative to RM ANOVA, because it does not require the dependent variable to follow a

Ranks	
	Mean Rank

a. Friedman Test

Figure 5 SPSS output for Friedman test statistics

normal distribution (Friedman, 1940). Developed by the US economist Milton Friedman, the test separates the data in tables comprising n rows by k columns. Then, the data are ranked across the rows and the mean rank for each column is compared. If we take the data in Table 1 as an example, the SPSS output which resulted after running the Friedman test is displayed in Figures 4 and 5.

In Figure 4 we see that in terms of rank order, baseline is the lowest, followed by 9 months, 6 months, and then 3 months. Compare this to the means in Figure 1.

Figure 5 contains the essential data that need to be included in reposting any findings for studies that analyzed data using the Friedman test: chi-square value, degrees of freedom (df), and p value (Asymp. Sig). The results are significant, because the p value is $<.000$, rounded to $.000$.

Regarding the sample size appropriate for running this test, it is very difficult to achieve a $p < .05$ with a sample size smaller than 12. Therefore, researchers should consider a number of participants larger than 12 for the Friedman test and larger than 30 for the RM ANOVA.

Competition Model

PING LI AND BRIAN MACWHINNEY

The competition model (CM) made its debut in Bates and MacWhinney (1982) as a mechanistic explanation of language acquisition. Since its inception, there have been a large number of studies using this framework to account for not only language acquisition but also language comprehension, language production, and impaired language processes. Because the CM distinguishes itself from many other psycholinguistic theories in its emphasis on language variation, the model has been applied to the analyses of many typologically different languages, including Chinese, English, German, Hungarian, Italian, Russian, and Spanish, to name a few. Like other scientific hypotheses, the CM has continued to evolve in order to increase its explanatory power (Bates & MacWhinney, 1987, 1989; MacWhinney, in press). Here we first provide an overview of the model and then discuss its application to the study of second language acquisition.

Cues and Cue Competition

A basic construct of the CM is the *cue*, an information source that allows the language user to successfully link linguistic form with meaning. Cues vary in their *type* (morphological, syntactic, prosodic, semantic, and pragmatic), *availability* (how often they are present), and *reliability* (how often they lead to the correct interpretation). Each cue is associated with *cue validity*, the joint product of availability and reliability, and crucially, the same cue may have different validity in different languages. For example, in English, word order (e.g., a noun before a verb) is a strong and reliable cue for identifying agent versus patient roles in an event (high validity), whereas word order is less predictive of who does what to whom in Chinese (low validity). Different languages may also utilize different cues to achieve the same goals; for example, in Hungarian, the suffix *-t* of a noun is a highly valid cue for predicting that the previous noun is a direct object, the recipient of an action, whereas in Chinese, the freestanding morpheme *ba* preceding a noun reliably indicates the direct object of a sentence.

A second key construct of the CM is that cues compete or converge in an utterance (hence the term “competition model”). That is, cues can point in the same or different directions for meaning interpretation in a sentence. In cases of competition, cue validity serves as the primary determinant of *cue strength*, that is, the weights that speakers assign to different cues during real-time sentence processing. For example, in the sentence *the elephant kicks the rock*, both word order and the animacy cue converge to point to *elephant* (preverbal, animate) as the agent of the action. By contrast, in the sentence *the rock kicks the elephant*, word order and animacy point to different nouns as the agent (word order favors *rock*, whereas animacy favors *elephant*). This divergence creates a competition between cues. In English, word order wins the competition (native English speakers reliably interpret *rock* as the agent), whereas, in Chinese, animacy wins the competition (native Chinese speakers generally interpret *elephant* as the agent; see Li, Bates, & MacWhinney, 1993). In general, sentence interpretation is facilitated when cues converge (shown in faster response time (RT) and higher accuracy) but impeded when cues compete (shown in slower RT and lower accuracy).

2 COMPETITION MODEL

Most of the empirical work within the CM framework relies on a sentence interpretation paradigm in which different sentences are created with orthogonalized cue combinations. For example, given a simple sentence of two nouns and a verb, there are three possible word order combinations: NNV, NVN, and VNN. Combined with the animacy cue (animate, A, vs. inanimate, I), these orders yield nine different conditions: AAV, AIV, IAV, AVA, AVI, IVA, VAA, VAI, and VIA. Systematic variation of the various cue types has allowed researchers to examine how cues collaborate and compete during offline and online sentence comprehension, how the same cues hold different validities in different languages, and how learners of a new language need to acquire new cue validities in sentence processing.

Second Language Learning

An important prediction of the CM with regard to learning is that cue availability and cue reliability may have different developmental trajectories. Cue availability is defined as the proportion of times a cue is available over the times it is needed, whereas cue reliability is the proportion of times the cue leads to the right answer over the total number of occurrences of the cue. In both L1 and L2 learning, cue strength is initially determined primarily by availability, because beginning learners are only familiar with cues that are relatively frequent in the language input (Taraban & Palacios, 1993; Matessa & Anderson, 2000). As learning progresses, cue reliability becomes more important than cue availability. To approach native proficiency, the learner needs to rely entirely on cue reliability for cue strength. In some cases, one can further distinguish the effects of *conflict reliability*: when two highly reliable cues compete, the one that wins the competition has a higher conflict reliability. For example, Dutch L1 learners only begin to realize after age 8 that the more reliable cue of pronoun case should dominate over the more frequent, but usually reliable, cue of word order (McDonald, 1986).

A second important prediction of the CM is that learners need to acquire new cue-strength patterns when learning a second language, and that depending on the language-specific properties of the speaker's L1 and L2, this acquisition may show different patterns. In a study of Chinese–English bilinguals who acquired their L2 at different ages, Liu, Bates, and Li (1992) examined how bilinguals assign thematic roles during online interpretation of sentences in L1 and L2. They identified four logical possible outcomes for adult bilingual learners: (a) differentiation: a clear separation in the use of cues for each language; (b) forward transfer: use of L1 cue patterns in the interpretation of L2 sentences; (c) backward transfer: use of L2 cue patterns in the interpretation of L1 sentences; and (d) amalgamation: an integrated pattern of cue use for both L1 and L2. The results of Liu et al.'s study were that late bilinguals showed clear forward transfer, in that they used their L1 cue strengths to interpret L2 sentences (e.g., relying more on semantics than word order in cases of cue competition). By contrast, early bilinguals, depending on the age of L2 acquisition, showed either differentiation or backward transfer. More importantly, there was no monotonic effect of age of acquisition, in that the teenager group exhibited stronger differentiation patterns than the early childhood group.

A given cue type may play different roles in different languages, leading to important implications for second language learning. Tokowicz and MacWhinney (2005) examined the ERP (event-related potential) responses of English–Spanish bilinguals who read sentences containing subject–verb agreement (similar in L1 and L2), determiner number agreement (different in L1 and L2), and determiner gender agreement (unique in L2). In both English and Spanish, subject–verb agreement is required, whereas determiner number marking differs in the two languages: English marks number only on the noun (*houses*) while Spanish marks number on both the noun and the determiner (*la casa* vs. *las casas*). ERP patterns showed that the English–Spanish bilinguals were highly sensitive to grammatical violations

in L2 for constructions that are formed similarly in L1 and L2 (subject–verb agreement), but were not sensitive to those that are formed differently in the two languages (determiner number agreement). In a similar ERP study, Chen, Shu, Liu, Zhao, and Li (2007) found that Chinese–English bilinguals showed high levels of accuracy in detecting subject–verb agreement violations in the L2 even though their L1 does not use any morphological agreement; however, their ERP response patterns differed from those of native English speakers in that no LAN (left anterior negativity) or P600 waveforms were present. These findings suggest that the particular cue strength from L1 may be ingrained in the late bilingual speakers, and that the L1 cue patterns negatively impact their processing in the L2, sometimes reflected not in behavioral but only in neural responses.

The Unified Competition Model

The CM is a model that highlights the dynamic interaction of cues in response to the processing environment, in which the statistical characteristics of the input and the learning characteristics of the language user jointly determine the processing outcome. The model has stimulated much crosslinguistic research, in both the monolingual and the bilingual context. Interestingly, while the model emphasizes that cue validities are highly variable and are different for users of different languages, it stresses that the underlying learning mechanisms are similar across L1 and L2 language acquisition. MacWhinney (in press) recently articulated this idea in the unified competition model (UCM), according to which the following constructs should be invoked to account for similarities and differences between L1 and L2 acquisition: maps, chunking, transfer, resonance, connectivity, codes, and mental models. Each of these constructs relies on additional tracks and traditions of research. For example, the account of lexical and grammatical maps is based on the DevLex model, a type of self-organizing neural network model of learning (Li, Farkas, & MacWhinney, 2004; Li, Zhao, & MacWhinney, 2007), as well as evidence from this work regarding the processes of entrenchment in neural networks (Zhao & Li, 2007, 2010). The account of chunking derives from the theory of item-based learning (MacWhinney, 1975, 1982). The model of connectivity derives from recent work in neuroimaging (Zhao et al., 2008; Friederici, 2009). The role assigned to codes and social participation comes from studies of social bases of learning (Firth & Wagner, 1998), and the role of mental models comes from recent work in cognitive linguistics (MacWhinney, 2008).

The UCM addresses the issue of similarities between L1 and L2 acquisition by emphasizing the extent to which second language learners must deal with the risk factors of entrenchment, negative transfer, social isolation, parasitism (dependency of L2 on L1), and mismatched connectivity (incorrect connections between processing areas). These risk factors arise from neurological, cognitive, and social configurations that change with development. The model also suggests how learners can make use of preventive factors to overcome these risks. The preventive factors include positive transfer, social participation or immersion, active thinking in the L2, reorganization through resonance (interactive activation from corresponding sites), and internalization (using L2 for inner speech). In order to achieve successful L2 acquisition using the same core mechanisms available to the child, the older learner must maximize the use of each of these protective factors. How these risk factors unfold in development and how learners can actively use the protective factors remain as the major challenges to theories of second language acquisition.

Complexity in Multilingual Systems

ULRIKE JESSNER

Introductory Remarks

Although multilingualism (or plurilingualism, to use a more Eurocentric term to describe the individual level) is by no means a new phenomenon, this field has only recently begun attracting a growing number of researchers. In a number of publications authors have referred to multilingual development as both a dynamic and a complex process. Today scholars are realizing more and more that in the study of multilingualism, the interaction of a variety of factors needs to be taken into consideration. The investigation of the complexity of multilingualism, a phenomenon which seems to lend itself to being approached from a dynamic systems theory (DST)/complexity theory (CT) perspective, has become one of the most challenging scientific undertakings of the linguistic academic community.

In the following we will consider the growing field of multilingualism and questions of definition before moving on to the variety of factors contributing to the complexity of multilingual systems. The main part of this entry deals with a dynamic systems theory approach to third language acquisition/multilingualism. We conclude with the call for an autonomous model of multilingualism in the field of linguistics.

The Research Scope of Multilingualism

The term “multilingualism” has been used with increasing frequency over the last few years. Yet, if we take a closer look at the publications that use the term, it quickly becomes clear that it is used to cover a range of meanings, some of which appear to be contradictory. Many still use the term “multilingualism” to refer to any system with more than one language. As bilingualism is the most commonly studied form of multilingualism, the two terms are used synonymously. An increasing number of researchers view third language acquisition (TLA) not as extended second language acquisition (SLA), but rather a different language-learning process in various respects (see Jessner, 2008a). As pointed out by Kemp (2009), the variety of terms and their origins derive from (a) the complex nature of use of various languages in a multilingual context and (b) the researchers’ backgrounds, ideologies, and purposes.

With the increase in interest in the field of multilingualism, several problematic issues, in particular with regard to terminology, have arisen. For instance, whereas in traditional SLA research the terms L1 and L2 are clearly defined, research on life-span development in multilinguals shows that the chronological order in which languages were learned is not necessarily the most useful factor in defining the L1, in the sense of “dominant language,” of a multilingual person. An L1 might become an L2 or L3 at a later phase in a multilingual person’s life due to a change of linguistic needs. The strong role that emotion can play in multilingualism can further complicate this classification. L1 might also denote the language of the heart, for instance the language somebody shares with her/his partner regardless of the level of proficiency in that language or the frequency of use.

Complexity and Diversity of Multilingual Development

As this discussion already shows, multilingualism is a challenging field, both because of the complexity stemming from diverse interdisciplinary interests and because of the number of variables involved in multilingualism. So far the field has been approached from different perspectives, such as on a sociolinguistic, psycholinguistic, and educational level. A DST/CT approach calls for the focus on the interdependence between all the variables in a multilingual system.

Since the mid-1990s, research on TLA or multilingualism has been increasingly intensified with the main goal of describing multilingual phenomena in order to investigate differences and similarities between second and third language acquisition (see, e.g., work by Cenoz, Hufeisen, and Jessner; De Angelis, 2007). So far studies have mainly been carried out in the fields of crosslinguistic influence, the cognitive and linguistic effects of bilingualism on learning further languages, multilingual processing, child trilingualism, and teaching of third languages. The field also includes studies concerned with the neurolinguistic aspects of the phenomenon (for a critical view see de Bot, 2008) or the economic value of language in a linguistic landscape (Cenoz & Gorter, 2008). In order to be able to judge multilingual development or multilingual conversation, all variables which contribute to multilingual development need to be taken into consideration, as suggested by DST. For instance, the number of possible acquisition routes increases with the number of languages learned. Whereas in SLA there are only two possible orders of acquisition—the two languages are acquired either simultaneously or sequentially—in the case of TLA we are confronted with at least four. Moreover, forms of learning are considered to play a crucial role in multilingual development. In contrast to SLA, TLA learning routes are much more diverse because very often forms of learning are of a mixed nature, that is multilingual learners study in both natural and instructed contexts.

Individual factors in language learning, such as motivation, attitudes, cognitive factors (e.g., aptitude, personality traits; see, e.g., Dewaele, 2010), as well as physical traits of multilingual learners (e.g., hearing capabilities), also contribute to the complexity of multilingualism and research of the phenomenon. Furthermore, during the life span of a multilingual person a variety of the factors involved can be subject to change, for instance motivation to learn one language may change (Dörnyei, 2009).

Dynamic Systems Theory and Multilingualism

The complexity and dynamics of multilingualism and multilingual development lend themselves to discussion within a DST or CT framework. With the support of new DST-based thinking avenues, several important issues in multilingualism have been identified.

In the dynamic model of multilingualism (DMM; Herdina & Jessner, 2002; Jessner, 2008b), DST/CT is applied to multilingual acquisition and use. Based on DST/CT principles, the development of a multilingual system is characterized by its nonlinearity, reversibility, stability, interdependence, complexity, and change of quality. Van Geert (1994, p. 50) states that “a system is, by definition, a dynamic system and so we define a dynamic system as a set of variables that mutually affect each other’s changes over time.” A multilingual system is adaptive and dynamic, which means it is able to change depending on the perceived communicative needs of the multilingual individual. Language attrition, a very common phenomenon of multilingual learning, is seen as an integral part of multilingual development, thereby illustrating reversibility in dynamic systems. Therefore, in contrast to reductionist approaches to language acquisition, in DMM it is stressed that multilingual

development is seen as complex, nonlinear, and variable due to its dependence on social, psychological, and individual factors.

The goal of the DMM is to serve as a bridge between SLA (process) and bilingualism (product) research, but at the same time to indicate that studies of multilingualism have to go beyond the scope of SLA and bilingualism. According to a DST approach the interaction between all the languages in a system needs to be foregrounded and recent studies in the area of TLA support this. Since the mid-1990s, an increasing number of scholars have conducted research on the differences and similarities between the processes in SLA and TLA. Evidence stems from studies on crosslinguistic aspects of TLA, where the status of the L2 in studies of TLA has turned out to be different from what would have been expected from traditional SLA research. From a number of investigations into transfer processes in multilingual learners it became obvious that in most cases the L2, and not the L1, as might have been expected, acted as supporter language in the case of both typologically related and unrelated languages (for an updated overview of the literature see De Angelis & Dewaele, 2009).

In contrast to monolingual learners, bilingual children show cognitive advantages in further language learning. Evidence of this was found in investigations into artificial language learning and a number of studies mostly in the European minority-language context such as Spain (Basque Country, Catalonia) and Finland (see Jessner, 2008a). In DMM it is argued that in the process of learning an L3 the learner develops a metasystem which is based on a bilingual norm, unlike SLA, where such a metasystem can only be based on the acquisition of the L1 and is therefore different in quality. In DST/CT terms this means that the multilingual system is considered sensitive to initial conditions which makes its development difficult to predict. An M(ultilingualism)-effect is assumed to develop as an emergent property in a changing multilingual system. This factor consists of language-specific and non-language-specific or cognitive skills which are used in the language-learning processes, language management, and maintenance. These skills and abilities which qualitatively differ from those in a monolingual can contribute to the catalytic effects in TLA, as found in experienced language learners (Kemp, 2007).

To sum up, in DMM a multilingual system is an open system, dependent on a variety of factors such as social and psychological ones. Language systems within the multilingual system are seen as interdependent (rather than as autonomous) systems because their behavior depends on the behavior of previous and subsequent systems and it would therefore make little sense to look at the various systems in isolation. In the following, stability of multilingual systems and holism as two major themes of a DST/CT approach to multilingualism have been selected for further discussion.

Stability of Multilingual Systems

As stated above, multilingual systems are constantly changing and their development includes both acquisition and attrition processes. If we take a long-term perspective of multilingual development (i.e., over the course of a multilingual's life), due to changes in the perception of communicative needs it is actually quite common that language knowledge in one language may begin to erode, due to enhanced contact with a new, further language. Learning an L3, for instance, can counteract the maintenance of an L2 or L1 or, in other words, language attrition or loss appear more often in multilingual than in bilingual biographies (see Todeva & Cenoz, 2009). In this case the L3 will become more dominant than the L2 due to limitations of resources for the use and maintenance of languages, as defined in Zipf's law of least effort (Zipf, 1968). As a result of this shift in language proficiencies,

the multilingual system loses stability. In DMM systems stability is related to language maintenance, that is the interplay of stability and variation needs to be focused on. Variability is used as a measure of stability because increased variability marks transition points in language development, so-called attractors (see also de Bot, Lowie, & Verspoor, 2007). If not enough energy and time are invested in maintaining a system, the system cannot be maintained, and it will begin to attrite. Other factors influencing systems stability include the number of languages involved, maturational age at which a language is learned and relative stability established, the level of proficiency at which this takes place, and the time span over which the language system is maintained.

A well-known example of such a stabilizing effect of a language system, very often but not exclusively at a rudimentary or restricted level of proficiency, is fossilization, a very common phenomenon in multilingual learning. The reasons for fossilization are complex and interrelated over time; in many cases they are related to domain specificity in bi- or multilingual contexts (see Larsen-Freeman, 2006, for a critical study of research on fossilization). But, even if parts of the multilingual system can become fossilized, that is, will—in very general terms—stop growing, they will still be able to exert influence on the other parts of the multilingual system.

A Holistic Approach to Multilingualism

Holistic approaches to bilingualism seem to be most frequently deployed in discussion deriving from Grosjean's idea of the bilingual as a competent speaker/hearer with very specific attributes (see, e.g., Grosjean, 1985), which provided part of the basis for Cook's work on the L2 user and multicompetence (see, e.g., Cook, 1992). Grosjean and Cook both argue for a perspective on bi- and multilinguals which places the focus not only on the specific skills developed via contact with two or more languages, but also on the non-applicability of monolingual norms in multilingual contexts and consequently in research on bi- and multilingualism. Additionally, in DMM it is argued that the multilingual system is in constant flux and that a holistic approach is a fundamental condition of a DST/CT approach. In this perspective, emergent properties of the open multilingual system (skills and abilities developed by multilingual users which are not to be found in monolinguals) have to be focused on as does the interdependence of all parts of the system.

Such an approach not only puts emphasis on a definition of multilingual proficiency based on a holistic understanding of the diverse components of the construct, but also stresses the interrelation between socio- and psycholinguistic aspects of multilingualism. From a DST/CT perspective the idea of nested systems contributes to an understanding of the relationship between two seemingly different approaches to the same phenomenon. In the case of language attrition in multilinguals the interdependence between these two aspects is obvious since it is changes in environment that eventuate in changes in linguistic knowledge (typically affecting the L1 of immigrant children). Language contact, more generally, as a complex phenomenon having emergent qualities, readily lends itself to being discussed from a complexity thinking perspective, as pointed out by Aronin and Singleton (2008). Similarly to Herdina and Jessner (2002), these authors claim that there are parallels between the concepts of complexity and recent findings and thinking in multilingualism. Increasing awareness and explicit recognition of the complexity of multilingualism allow for a more comprehensive theoretical understanding of multilingualism as well as yielding practical results in the teaching of multiple languages. Along with liminality and suffusiveness, complexity is an inherent emergent property of contemporary multilingualism that calls for the development of appropriate new research approaches. Among the sources for the latter would be the methods of complexity science (Aronin & Hufeisen, 2009).

Outlook

From the above discussion it has already become quite obvious that a DST/CT approach to multilingualism needs to be complemented by DST/CT research methodology. As early as 2002, Herdina and Jessner stated that an autonomous model of multilingualism needs to be developed in order to do justice to the complex nature of multilingualism.

To achieve this goal it is necessary that not monolingual but multilingual norms be applied in multilingualism research. Yet at the moment, only a small number of scholars seem to realize what such an approach entails for research on multilingualism. To date, most linguists continue to apply monolingual norms when it comes to research on bi- and multilingualism, which means among other aspects that native-speaker language proficiency is still used as the yardstick for all the languages of the multilingual person, and multilingual subjects and their languages can be investigated without taking all the languages in contact into consideration (see, e.g., De Angelis & Jessner, in press).

For future research it is therefore hoped that the complexity of multilingual development is acknowledged and consequently approached from a DST/CT perspective which is able to focus on nonlinearity and variability.

Compound Words

EMILIANO GUEVARA

Compounding is one of the two main processes of word formation in natural languages (the other one being derivation by affixes). In short, compounding creates a new word by joining together two or more independent words (cf., among many others, Bauer, 2001); the newly created compound is typically a hyponym of one of its constituents, which is called the *head* of the compound. For example, given the independent simple nouns *dog* and *house*, a speaker of English is able to form the compounds *doghouse* and *house dog*, respectively headed by *house* and *dog* (i.e., a *doghouse* is a type of *house* and a *house dog* is a type of *dog*). The remaining constituent in a compound is called the *modifier*.

Although compounds behave like words (e.g., they show the distributional patterns of words, they cannot be separated in discourse, etc.), they also clearly show some combinatorial properties that constitute a sort of “internal syntax.” Compounding (especially nominal compounding) is a recursive process which can be applied to its own output, thus creating compound words of increasing complexity, for example, *plastic doghouse*, *plastic doghouse sale*, *plastic doghouse sale committee*, and so on. This feature of compounding makes it an extremely powerful and creative means of word formation, particularly efficient for the creation of specialized terminologies.

While the prototypical compound word is formed by combining two nouns ($N+N \Rightarrow N$), there exist many different productive patterns of compounding in the world’s languages (for an overview see Guevara & Scalise, 2008). As an illustration, consider the following English examples: *underclothing* ($P+N \Rightarrow N$), *speaking-box* ($V+N \Rightarrow N$), *high school* ($A+N \Rightarrow N$), *bitter sweet* ($A+A \Rightarrow A$), *ice cold* ($N+A \Rightarrow A$), *above-mentioned* ($Adv+A \Rightarrow A$), and *sky dive* ($N+V \Rightarrow V$).

As simple and fundamental as it may seem, compounding is an intensely debated topic in theoretical linguistics. The very nature of compound words is the main reason for this disagreement: compounds stand half-way between word-formation (morphology) and syntax, and scholars have not been able to establish whether compounding belongs to one of these grammatical modules, or if it constitutes a different, specialized module in its own right. Even the very definition of compounding becomes a difficult task when one considers some special cases including at least one constituent that is clearly not a word. This is the case of *neoclassical compounds* such as *biohazard*, *astrophysics*, or *bibliography*, where the constituents *bio-*, *astro-*, *biblio-*, and *-graphy* are bound stems (i.e., not attested as independent words) of Greek and Latinate origins. An even more serious problem for the definition of compounding is posed by the so-called *phrasal compounds*, which are characterized by having a complex modifier that clearly seems to be a syntactic object, for example *God-is-dead theology*, an *ate-too-much headache* (cf. Lieber, 1992). This ambiguous status of compound words between morphology and syntax has been further elaborated by Jackendoff (2009), who claims that they are in fact a relic of protolanguage, providing us with an insightful point of view into earlier stages in language evolution.

The interest in compound words has a long history, with the first known exposition by the Sanskrit grammarian Pāṇini (fourth–fifth century BC). One of the aspects that has attracted the most interest is the classification of compound types (see Bauer 2001; Bissetto & Scalise, 2005). Besides the above mentioned neoclassical and phrasal compounds, a

2 COMPOUND WORDS

number of other types have been identified with various criteria. For example, the so-called *synthetic compounds* (e.g., *truck driver*, see Lieber, 1992) are formed by a deverbal head (*drive* + *-er*) and a modifier that corresponds to the internal argument of the head's verbal base (*drive a truck*). Focusing on a single criterion, that is, the grammatical/semantic relation between the constituents, Bisetto and Scalise (2005) identify three main types of compounds: *subordinate* (the modifier stands in a dependency relation with the head, e.g., *doghouse* = "house of/for/with a dog"); *attributive* (the modifier functions as a mere attribute of the head, being almost emptied of its original meaning, e.g., *swordfish*, where *sword* means only "long and sharp"); and *coordinate* (where both constituents stand in a relation of coordination, as in *poet-painter*). Furthermore, some compounds do not seem to have a head at all, for example, *pickpocket* (V+N=>N, but *pickpocket* is not a type of *pocket*): they are called *exocentric compounds*.

Compounding is an interesting phenomenon also for other sciences, in particular for cognitive psychology and for psycholinguistics. Since compounds are usually formed by two constituents, and since most regular compounds are semantically transparent, compounding as a whole is a perfect window into the complex mechanisms of the mental lexicon. Cognitive psychologists have paid particular attention to the subtleties of conceptual combination and interpretation of nominal compounds (see Gagné & Shoben, 1997; Wisniewski, 1997; Estes & Glucksberg, 2000). Psycholinguists have concentrated instead on the mental representation and processing of compounds (Are they stored/accessed as single units or as separated constituents? Are frequent compounds processed faster?). For a wide-ranging overview of these issues, see Libben & Jarema (2006).

Compounding has recently also attracted some attention in computational linguistics. The aspects that have been treated so far regard the automatic segmentation and structural analysis of multiconstituent compounds such as the famous German example *Donaudampfschiffahrtsgesellschaftskapitän* 'Danube steamship company captain.' More recently, also, the automatic induction of compound semantics has been an object of study, see Lauer (1995) and Ó Séaghdha (2008).

Computer-Assisted Pronunciation Teaching

DOROTHY M. CHUN

Although the teaching of pronunciation does not appear to be one of the top priorities for most language teachers at the beginning of the 21st century, it is an important aspect of spoken language that cannot be ignored in view of globalization, the growing needs of cross-cultural communication, and issues of speaker identity and social integration. Second language speakers need not only to make themselves understood but to be able to understand both native and non-native speakers of their second language (L2). Instead of the more traditional focus on acquiring a native-like accent by practicing difficult sounds, it is a widely held opinion that the current focus should be on intelligibility and comprehensibility, acknowledging both the rarity of acquiring native-like pronunciation and the nonstandard variations in all languages. A growing body of research indicates that the melody and rhythm of language, rather than individual vowels and consonants, are more important for understanding and producing a language that is not one's native tongue or first language (L1). In order to help learners improve their perception and production of melody and rhythm of the L2 being learned—as well as of individual L2 sounds—computer-assisted pronunciation teaching has proven to be an effective means. The computer's capacities for unlimited input, practice and repetition, for individualized and instantaneous feedback, for both listening and speaking activities, and for providing a visualization of tone and intonation contours make it a useful tool for teaching pronunciation.

Technology for Teaching Segmentals (Vowels and Consonants)

Extensive research on the acquisition of L2 vowels and consonants has been conducted (Lively, Logan, & Pisoni, 1993; Flege, Bohn, & Jang, 1997; James & Leather, 1997; Kingston, 2003, to name only a very few), but computers were often used only to conduct the studies and analyze the data rather than as training tools.

Studies that use computer-based training materials for segmentals are emerging, and training can include perceptual, acoustic, articulatory, or some combination of the three types. For example, Wang and Munro (2004) noted that “a limited range of speech sounds have been examined, with a disproportionate number of studies considering only consonants” (p. 539), prompting them to investigate computer-based training techniques with Chinese speakers learning English vowel contrasts. Learners were trained both in the perception and production of vowels, and in comparison with an untrained group, trainees showed improved perceptual performance and maintained their improved production three months after the training.

Feedback

The need for feedback is well documented in second language pronunciation research (Leather, 1983). The traditional record-play exercises in language laboratories that have existed for decades enabled learners to listen critically to replays of their production, in

2 COMPUTER-ASSISTED PRONUNCIATION TEACHING

the hope that they would improve their pronunciation. However, in practice, this required learners to monitor themselves even though they generally lack the phonetic criteria for critical listening (see Gómez et al., 2008, for a discussion of feedback loops connecting speech perception and speech production). One solution using computers is to provide real-time feedback to the learner in the form of visual displays of articulatory activity and its acoustic consequences in actual speech output.

In contrast to precomputer technologies for teaching and practicing pronunciation, which only used the *auditory* and oral channels, computers have been used since the 1960s for analyzing and *visually* displaying human speech for linguistic and pedagogical purposes (Delattre, 1963). While spectrographic analysis at that time was a painstaking process, it has become relatively easy technologically to digitize, process and analyze the acoustics of spoken language. Computers today are equipped with hardware to digitally record speech, and free software exists for processing the digital files. Figures 1–3 below were created with the free digital audio editor Praat, available for Windows, Mac, Linux, and other Unix-like operating systems. Other widely used free programs include Audacity, ENHANCE, RTSPECT, SFS, Speech Analyzer, WASP, and Wave Surfer, to list a few (Godwin-Jones, 2009).

Visual Acoustic Displays

Waveforms are graphical representations of sounds, i.e., graphs of a signal's sound pressure over time. Motohashi-Saigo and Hardison (2009) explored the value of using waveform displays as visual feedback to L2 learners of Japanese geminates (doubled vowels and consonants) and found significant improvement in perception (identification) following training, especially when learners received both auditory *and* visual feedback. Figure 1 shows a waveform of the word “ah” repeated three times.

Spectrograms display the acoustic features of sounds, with the most common format being a graph showing time on the horizontal axis and frequency (of vocal fold vibration) on the vertical axis. In addition, a third dimension indicates the amplitude (or loudness) of a particular frequency at a particular time, represented by the intensity or color of each point in the image. Figure 2 shows a spectrogram of the word “ah” repeated three times whose waveform is shown in Figure 1. Figure 3 shows a spectrogram of the word “oh” repeated three times. Although “ah” [a:] and “oh” [o:] are different words with different meanings, if a learner were to see only the spectrograms, it would not be clear how the pronunciation is actually different or what the learner would need to do in order to produce the two words correctly. In other words, although technology can visually display acoustic differences, if learners are not expert at “reading” the spectrograms or at understanding how the formant frequencies (harmonic frequencies or acoustic resonances) are

Figure 1 Waveform of “ah.” Created with the digital audio editor Praat (praat.org)

Figure 2 Spectrogram of “ah.” Created with the digital audio editor Praat (praat.org)

Figure 3 Spectrogram of “oh.” Created with the digital audio editor Praat (praat.org)

articulated with the tongue, such displays will not be immediately or intuitively useful. It should also be noted that formant representations are primarily of use in displaying the characteristics of vowels, but they cannot be created for voiceless sounds and are therefore not of use for depicting voiceless consonants.

In addition to the problem of interpreting the difference between the spectrograms of the “ah” and “oh” vowels in Figures 2 and 3 above, there is a difference in the duration of the two words, which in turn makes it difficult to compare the spectrographic information. This illustrates a common problem with software programs, which purport that learners simply need to compare their pronunciation with that of a native speaker. In the case of comparing spectrograms, if the duration of the sound or word is not identical to the native-speaker model, then it is even more difficult for learners to ascertain how and why their pronunciation is incorrect. Gómez et al. (2008) and Molholt and Hwu (2008) propose that such visualization can be helpful to learners, but targeted training is critical.

Visual Articulatory Displays

In contrast to acoustic waveform or spectrographic analyses, perhaps of greater use to learners are articulatory explanations and visualizations, i.e., descriptions of how sounds and words are articulated or produced by speech organs, including the lips, tongue, teeth,

Figure 4 Images from the University of Iowa's Phonetics Flash Animation Project Web site, showing the project logo and sample video of a sound spoken in context. <http://www.uiowa.edu/~acadtech/phonetics/> © The University of Iowa

and the oral and nasal cavities. Many free Web sites today show articulatory mechanisms in great detail. For example, the University of Iowa's Web site does an excellent job of showing how sounds and words in American English, German, and Spanish are produced (<http://www.uiowa.edu/~acadtech/phonetics/>). With the use of video animations of the speech apparatus, learners can simultaneously hear the sounds and see how the tongue, lips, and uvula move (see Figure 4).

De la Vaux and Massaro (2004) studied facial movements and gestures, systematically manipulating the amount of visual information presented to a listener in testing and training word and phoneme recognition. A study by Hardison (2003) proposed that since the presence of visual cues from a talker's face is beneficial for the improvement of L2 perceptual accuracy, attention should be focused on the talker's lip movements in improving speech and pronunciation, for example, by using video within computer-based pronunciation training. Cosi, Cohen, and Massaro (2002) experimented with computer-animated conversational agents with potential applications to tutoring second language speakers.

Automatic Speech Recognition (ASR)

In an excellent review of research and software for computer-assisted pronunciation training (CAPT), Neri, Cucchiaroni, Strik, and Boves (2002) proposed that ideal CAPT courseware should provide input, output, and feedback, and should incorporate automatic speech recognition (ASR) technology. They observed that available technology is capable of meeting pedagogical requirements, but concluded that "many commercial systems tend to prefer technological novelties to the detriment of pedagogical criteria that could benefit the learner more" (p. 441). Specifically, they found that the issue of feedback remains problematic and note that current ASR technology can only provide a limited amount of detail in error diagnosis. Other studies echo similar limitations, e.g., Levis (2007) and Derwing, Munro, and Carbonaro (2000), who found that automatic speech recognition for non-native speakers was 24–26% lower than for human listeners, suggesting that ASR software would provide unreliable feedback to second or foreign-language learners (p. 597). The issue of appropriate and sufficient feedback will be discussed further in the following section.

In summary, computer software has been used for training in the perception and production of L2 sounds (vowels and consonants). Visualizations of articulatory processes, i.e., how speech sounds are produced by human speech organs, and of the resulting acoustic product, i.e., spectrograms and waveforms showing vowel qualities, loudness (intensity) and duration, have been found to be effective to some degree. However, despite the enormous progress that has been made in terms of speech recognition, the feedback provided by ASR software is not as accurate or as helpful as it theoretically could be. This is an area that requires further research and development. In addition, there is to date less

research on vowels than on consonants; yet, vowels are of critical importance to having an “accent” as well as to the melody and rhythm of language, as they are generally the carriers of pitch and duration, which in turn contribute to stress and rhythm. The following section discusses CAPT programs for suprasegmentals.

Technology for Teaching Suprasegmentals (Prosody, Intonation, Rhythm)

Current research both in L2 phonological acquisition as well as in the use of computers for pronunciation training (including ASR) is focusing increasingly on suprasegmentals or prosody (Chun, 2002; Jenkins, 2004). Key areas of investigation to be discussed in this section include foreign accent, intelligibility, comprehensibility, fluency, and discourse intonation.

A common and realistic goal of second language learners is to achieve a level of pronunciation sufficient to be understood in their L2. Although a non-native accent can sometimes interfere with this goal, simply having an accent is not necessarily a barrier to communication. Munro and Derwing (1999) found in a seminal study that “even heavily accented speech is sometimes perfectly intelligible and that prosodic errors appear to be a more potent force in the loss of intelligibility than phonetic errors” (p. 285). They define intelligibility broadly as “the extent to which a speaker’s message is actually understood by a listener” though there is no universally accepted way of assessing it (p. 289). Intelligibility is distinguished from comprehensibility in that the latter refers to the listener’s *perception* of how much they have understood or the ease with which they could interpret an utterance. A listener’s perception of accent may be different from the same listener’s judgment of comprehensibility. In a classroom experiment in which one group of ESL students received segmental instruction and a second received suprasegmental instruction, Derwing, Munro and Wiebe (1998) found that only the second group’s extemporaneous production improved in comprehensibility, meaning that listeners found them to be easier to understand (see also Tanner & Landon, 2009). In theory, CAPT could be used for suprasegmental instruction for the purpose of improving L2 speakers’ comprehensibility.

Visualization of Suprasegmentals

Researchers have studied how intonation carries meaning both at the sentence level and at the discourse level and helps to create cohesion in discourse (Wennerstrom, 1998; Pickering, 2001). Researchers and teachers alike have been advocating that intonation be taught in second and foreign-language classes (Chun, 1998), and there is evidence that presenting displays of pitch contours improves both perception and production of tone (e.g., in tonal languages such as Mandarin Chinese) and intonation (de Bot & Mailfert, 1982; Molholt & Hwu, 2008). But two main obstacles hinder the teaching of intonation. First, most teachers do not themselves know enough about suprasegmentals to be able to explain them to their students, and second, prosody is a very complex phenomenon, as it involves many different aspects of speech, including stress, rhythm, and intonation. How to quantify each of these prosodic components is also very difficult. One of the possible solutions to quantifying these features is to use visualizations of the acoustic manifestations of these components, e.g., a graph showing fundamental frequency (or pitch) curves that display the melody of speech on the y-axis, along with time on the x-axis showing the duration or length of syllables or words (see the lower part of Figure 5). Another possibility is waveforms that display the intensity (loudness, the amount of energy given to each syllable) as well as the duration of individual sounds, words, or periods of silence (upper part of Figure 5).

Figure 5 Waveform and pitch curves of two utterances “Oh.” Created with the digital audio editor Praat (praat.org)

Levis and Pickering (2004) examined sentence-level versus discourse-level intonation and recommended that technology be employed to teach intonation at the discourse level, stating “While the use of visualization technology is a crucial advance in the teaching of intonation, such teaching can further be enhanced by connecting technology to an understanding of how intonation functions in discourse” (p. 505). They provided some specific examples of how systematic meanings of pitch movement can be described in transparent ways to learners, and pointed to the reality that software is now capable of presenting longer stretches of speech. Yet, it is also true that the unlimited number of situations and contexts allows for a large number of appropriate intonational patterns, e.g., the “Oh . . .” on the left in Figure 5 might be uttered when a speaker is reacting hesitantly or skeptically, whereas the “Oh!” on the right indicates a certain degree of surprise. Instructors and software would need to explain the (numerous) possibilities.

Hardison (2004) reported on a study of using visual feedback provided in a computer-assisted program to help in the acquisition of French prosody by foreign-language learners (L1 English). The software provided pitch displays of native-speaker exemplars and real-time displays of learners’ utterances and proved effective not only in improving the learners’ pronunciation of the trained utterances but also of novel sentences. In addition, segmental production improved, and learners noted increased confidence in their oral production of French, and heightened awareness of the elements that make up speech.

In a German phonetics course that included a focus on improving learners’ intonation, Chun (2008) had her students use TELL ME MORE software (<http://www.tellmemore.org>).

Figure 6 TELL ME MORE software's display of pitch curves. <http://www.tellmemore.com>
© TELL ME MORE

com) to practice sentence intonation (see Figure 6). The ASR component of the software displayed the pitch curves of a learner's utterance (blue line) in real time. The learner could also see the movement of the lips and other speech organs as well as an assessment in the form of (1–7) green bars. Although studies such as Hardison's (2004) reported that these types of visualizations could improve pronunciation, students in the German phonetics course tended to look only at the number of bars they received for their utterance and not at the pitch contours. If they received the maximum number of bars possible, they went on to the next item, without noticing whether their pitch contours matched those of the native speaker. Even after students were instructed to draw the native speaker's pitch curve along with their own on paper, they were not able to explain how their contours differed from the model's. This suggests that learners must be trained explicitly in how to use the visualizations of their pitch contours to notice and improve their pronunciation. These training features must be incorporated into software programs for learners but are not currently available in the great majority of programs.

An excellent online program for advanced learners of English is Streaming Speech (<http://www.speechinaction.com/>), based on Brazil's theory of discourse intonation and on sound pedagogical principles. The speech samples are all unscripted narratives that have been meticulously and extensively "re-purposed" for pedagogical use. Learners can observe the direction of pitch changes that are schematically drawn, as in the example in Figure 7. The use of authentic speech is in stark contrast to the vast majority of programs for pronunciation that use stilted, unnatural-sounding recordings, though this may be effective primarily for advanced learners.

Figure 7 Streaming Speech software. <http://www.speechinaction.com/> © Streaming Speech

Use of Videos

Computer programs can provide not only visualizations of speech but also videos of speakers speaking. A study by Hardison (2005) was conducted with L1 speakers of Mandarin Chinese who were advanced L2 speakers of English. Their pretraining difficulties with English prosody involved some of the discourse functions of intonation that contribute to the cohesion of speech, namely the marking of thought groups with appropriate pausing and pitch movement, and the use of stress and intonation to mark information focus. The study investigated the effects of different types of contextualized training using segments from the participants' own oral presentations on the production of discourse-level English prosody. Two computer-based tools were used to compare training with and without the visual context of the speech event, and with discourse-level input versus isolated sentences. The first tool was the Web-based Anvil (Kipp, 2001), which provides a screen display integrating the audio and video components of a speech event with the associated pitch contour created by the public domain phonetic tool Praat (see Figure 8). Results showed that the presence of the video was helpful, more so with discourse-level input than with individual sentences, strongly suggesting that meaningful contextualized input, as provided for example by video, is valuable for prosody training.

The second tool was the Real-Time Pitch program in conjunction with the Computerized Speech Lab, which produces a pitch contour in real time and allows on-screen comparison of a learner's utterance with that of a native speaker, including overlay of one contour on another (see fig. 3 in the article at <http://llt.msu.edu/vol8num1/hardison/default.html>). These programs are both commercial products of KayPentax (<http://www.kaypentax.com>).

In summary, technological tools are widely accessible for creating software that can help L2 learners by (a) displaying acoustic information about their utterances (e.g., pitch curves) as compared with native-speaker utterances and (b) displaying video clips of native speakers' facial movements and body gestures, which provide helpful nonlinguistic and contextual information. In addition, the W3C's (World Wide Web Consortium) efforts to implement commonly accepted standards are helping on the technical side (Godwin-Jones, 2009). But the main obstacle is that ASR is not yet able to provide the kind of detailed diagnosis of learners' mispronunciations and meaningful feedback that would allow learners to understand precisely what is incorrect or mispronounced. Furthermore, the expertise of teachers in collaboration with programmers is needed to create such software with the accompanying helpful feedback.

Figure 8 Web-based Anvil software. <http://www.anvil-software.de/> © Anvil

Outlook for the Future

Given the technological capabilities that exist, an ideal CAPT program would combine auditory and visualization features, automatic speech recognition (ASR), and appropriate and accurate feedback. Hincks (2003) proposed “oral skills software using an animated agent, a talking head, as an intelligent language tutor. Such a tutor would need to be endowed with sophisticated speech recognition in order to ‘understand’ students, and natural-sounding speech synthesis in order to communicate with them. As we have seen, speech recognition has a way to go before meeting these goals” (p. 18). However, if L2 researchers and teachers were to collaborate closely with acoustic phonetic and ASR programmers (computer scientists and engineers), they could together resolve issues such as reconciling differences in the speed of speech between a non-native learner and a native-speaker model, meaningfully describing and visually pinpointing problematic differences between learners and native-speaker models, and finally, but importantly, embedding practice into more authentic, contextualized speech situations.

A critical but nontechnological issue that needs to be dealt with is teacher training. Derwing (2008) noted that only a small percentage of language teachers have had any formal pronunciation teaching, so this must change even before teachers consider using technology to help with pronunciation teaching. Levis (2007) stated that teachers need to have a basic understanding of the types of technology that are used in phonetics research and that they “should have the opportunity to develop and test their own computer-based pronunciation exercises through the use of basic CALL authoring tools” (p. 196). Instructors will need to learn to use these authoring tools and collaborate with discourse intonation specialists and computer scientists to design pedagogically sound activities and exercises (Dalby & Kewley-Port, 2008; Precoda & Bratt, 2008).

Finally, there are broader social issues that must be considered, including which language variety or dialect will be taught with CAPT programs, whether multiple variants and accents will be included in a program, and the acceptability of speakers to maintain their identity as L2 speakers. The goals of pronunciation training might then shift from acquiring unaccented speech to targeting intelligible, comprehensible speech. To be sure, negative societal (or individual) reactions to accented or non-native speech that affect integration of L2 speakers will not be changed or even ameliorated by CAPT software, no matter how sophisticated or effective it becomes.

Computer-Assisted Language Learning and Machine Translation

HAROLD SOMERS

Introduction

Machine translation (MT) is the oldest application of what is sometimes called “language engineering,” and has been around for over 60 years. While not fulfilling the early promise of “fully automatic high-quality translation of unrestricted texts,” the technology has now reached a stability and a maturity, where developers and experienced users well understand the capabilities and limitations, and, in general, present these honestly to the general public.

This entry concerns the role—potential and actual—of MT in the teaching of languages. We will first discuss and clarify what we mean by “machine translation,” and briefly survey the state of the art, concentrating mainly on commercial and freely available MT tools. A reminder of the limitations and difficulties associated with MT systems will be a useful preface to the sections that follow.

Our discussion of the role of MT in language learning will begin with a comment on the use of translation per se in the language classroom. We will then discuss the importance of teaching about MT and related tools to language learners as potential translators, before focusing on the use of MT as a classroom device for language learning. Finally, given the widespread availability of free MT tools on the Internet, we address a recently emerging problem of language learners using MT tools to complete translation and other writing tasks, how this type of plagiarism can be spotted, and whether MT has a more positive role to play in the language classroom.

What Is Machine Translation?

For the most part in this entry we will understand “machine translation” to mean computer software which takes a text written in one language and attempts to translate it, largely without any intervention by a human user, into another. Apart from a brief mention, we will not refer to tools for computer-assisted translation which may or may not attempt some part of the translation task but largely leave it to the human translator to make the important decisions; nor will we comment on the newly emerging technology of spoken-language translation, which as yet is of insufficient maturity to have a significant use in the classroom.

MT technology is now widely available for dozens of languages either free on the Internet, included as part of the package on new computers, or as stand-alone software available at prices ranging from trivial to significant. By far the widest use of MT is by nonlinguists for translating Web pages and e-mails. Users should understand that the translation quality is entirely dependent on the nature of the source text and may range from acceptable without revision (for texts using a limited vocabulary and simple syntax), through adequate for gisting purposes, to almost incomprehensible.

Historically, MT system development has seen two major approaches, which are characterized as “rule-based” and “statistical.” Rule-based MT systems consist of programs which apply, as the name suggests, packages of linguistic rules to analyze the input text and convert it into the target language. These rules are developed by teams of expert linguists and represent a massive investment by the MT system producers. The statistical approach on the other hand depends on automatically extracting from huge amounts of parallel data (millions of words of translations, usually aligned sentence-by-sentence) statistical parameters capturing the probabilities of word and phrase correspondences. Statistical MT systems typically do not encode explicit linguistic information, but learn it from analyzing many examples. The latter approach has for the last 20 years overwhelmingly dominated MT research, though a small number of commercially available MT systems are rule-based, and the market leader, Google Translate, uses mostly statistical approaches, which are now beginning to dominate. The significance of this difference will become apparent in later sections.

Whichever approach is taken, state-of-the-art MT systems still have many weaknesses, so much so that it is generally agreed that while they may be suitable for “assimilation,” for example getting the gist of a text written in a foreign language, they are insufficiently accurate for the production of high-quality text if the user does not know enough of the target language to check for bad translations. Ironically, it is these weaknesses in MT that most lend themselves to its use as a language-teaching tool.

The main weaknesses stem from the inherent ambiguity of natural language: in “lexical ambiguity,” individual words can have a variety of meanings and hence translations which cannot always be inferred from the context. Lexical ambiguity can result from polysemy (where a word has several related meanings) or homonymy (where the different meanings are unrelated) in the source language, or from the fact that a word in one language can have a variety of translations in another, just because the target language makes distinctions that the source language does not. So a typical MT error is to choose the wrong target word.

“Structural ambiguity” can arise when a sequence of words has more than one possible interpretation, which again can lead to a different translation. This can be related to lexical ambiguity, as in the famous example *Time flies like an arrow* (the ambiguity lies in which of *time*, *flies*, or *like* is the verb), or can come from scope or attachment ambiguities as in *young men and women* (are the women young?) and *He saw the girl with a telescope* (who has the telescope?).

Taken together, these kinds of problems can simply overload the MT system and result in poor, “stilted,” or even incomprehensible translations. On top of this, for some language pairs, the source language may be underspecified with respect to the target language (e.g., some languages do not distinguish singular and plural), with obvious ramifications for translation.

Translation as a Language Skill

One issue relating to the use of MT for language teaching is whether translation itself is a useful activity (see Cook, 1998). The so-called “classical” grammar–translation method is almost universally derided these days, though perhaps this is more for its approach to the teaching of grammar than to its use of translation. Furthermore, in this approach, translation is L2–L1, texts are usually chosen for their literary merit, and the aim is to ensure comprehension and, perhaps, to improve L1 writing skills.

Newmark (1991) identifies various aims behind translation as a language-learning exercise, depending on the stage the learners are at: as a form of control and consolidation

of basic grammar and vocabulary in the elementary stages, in the middle stages as a way of combating interference, interlanguage or unconscious translationese, and for advanced learners as a skill in itself (Newmark, 1991, pp. 61–2). He also identifies it as a means of improving “style,” of increasing vocabulary and “flexibility in switching grammatical shifts,” and he mentions two further uses focusing on communicative appropriateness, social style and register, and what he calls “semantic” translation, focusing on unusual collocations, metaphors, neologisms, words and grammatical constructions used in a special or unusual way.

Whichever the translation direction, self-correction is claimed to be good, though quite difficult. If correcting errors is a good exercise, then MT is a good source of such errors, as we will discuss in the next section.

Campbell (1998) writes at length on the competence to translate into the L2 as a measure of L2 acquisition, and that translation exercises can give some insight into interlanguage development. He expresses his surprise that “translation studies [have] virtually ignored the idea of interlanguage” (p. 13), even though there are many resonances. Translations produced by learners represent a linguistic system in some degree separate from both L1 and L2 systems. One argument is that by setting a translation into the L2 (rather than, say, a free composition), one can control the vocabulary and structures that are tested. Another, much weaker, argument is that translations are easier to mark, because of the existence—at least notionally—of a “correct” model. More realistically several more or less correct models will exist, depending on the level of the student.

If translation is an activity that language learners expect to engage in professionally, then there is a place for translator training in language learning. Furthermore, however useful an activity translating is for language learning—and opinion on this has fluctuated over the years—it seems to be a natural thing for learners to want to do, and seems to be an inevitable part of most language curricula, both into and out of the L2.

MT and Trainee Translators

Irrespective of whether translation in itself is a skill that many language learners may appreciate learning and practicing, translation is one possible (professional) use of a student’s language abilities. It is therefore not contentious to state that language learners “need to know what the capabilities of state-of-the-art MT are and how to evaluate its role as a practical tool in the language industry” (Lewis, 1997, pp. 255–6). Awareness of translation technologies by trainee translators is the focus of some of the earliest literature on the use of MT in the language classroom that we have been able to find, as typified by a series of articles by Loffler-Laurian (1983, 1985, 1987) which are nevertheless rather general in nature. Like many writers who followed her, Loffler-Laurian highlights the need for trainee translators to be aware of technological advances, the role of post-editing and revision, and above all the question of style and “the adaptation of style to the specific needs of communication” (1983, p. 96, my translation). She suggests that MT output can be useful in reconsidering the traditional notions of “mistake” and “error.”

Awareness of MT and computer-based tools for translators is now an important element of translator training, usually at the undergraduate and graduate levels. Somers (2003a) surveys some of the approaches that have been taken, including hands-on training, awareness of controlled language applications, system dictionary updating, simulation of workflow scenarios (see also Hartley & Schubert, 1998), teaching of post-editing skills (see La Torre, 1999; O’Brien, 2002), and evaluation of MT output.

MT in Language Learning

Besides its role in translator training, there have also been a number of proposals to use MT as a language-learning tool. Of course there is something a little odd in trying to use a tool for a purpose for which it was not intended (even though some early commercial MT software systems promoted their use also as a language-learning aid, and the software included grammar tutorials, for example lists of inflection paradigms). Nevertheless, some of the proposals for use have been quite ingenious. Predominant among the reported uses is the idea of taking MT as a bad model, using its errors and shortcomings to bring out some aspects of linguistic differences. MT evaluation and revision (post-editing) of MT output as a language-learning exercise similarly focuses on MT's weaknesses, though perhaps in a more sympathetic approach. Finally, we will also look at how some translation tools can be used in the language classroom, and the use of MT in language training for specialists in other fields.

Using MT as a Bad Model

MT software first became generally available in the mid-1980s, before personal computers were widely used, and so access to MT was obviously somewhat restricted. Nevertheless there were some early pioneers keen to exploit the technology. The quality of the output was then sufficiently low that the prevalent view was typified by Higgins and Johns, who said of MT systems that "as language learning aids they are woefully inadequate, but . . . might provide a teacher with an interesting peg on which to hang a discussion of grammar, asking the students to spot the machine's howlers and account for them" (Higgins & Johns, 1984, p. 95).

This idea of MT as a "bad model" is quite widely found, where its weaknesses and mistakes are used to bring out subtle aspects of language differences or to reinforce learners' appreciation of both L1 and L2 grammar and style. For example, Ball suggests that "withholding the source text and inviting the student to *reconstruct* it from the raw translation . . . can be quite useful for drawing attention to half-forgotten points of grammar and usage" (Ball, 1989, p. 52; emphasis original).

Anderson (1995) describes use of a bidirectional English-Hebrew MT system in this way. Students manually entered sentences provided to them one by one, noted the results, and then used native-speaker intuition and/or L2 reference works (depending on the translation direction) to identify and correct the errors. For translation into the L1, this can be a useful exercise, since the poorer-quality translations are usually too close to the lexical and syntactic structure of the source language, and this exercise can reinforce the students' awareness of differences between the languages by showing them a bad translation into their own language.

Richmond (1994) likewise uses the MT system to bring language contrasts to the attention of students by again providing sample texts for translation into L2 along with model answers. Students are asked to type in the original L1 sentence, and note that the system gets the translation wrong. They are then asked to try to modify the sentence and retranslate it, continuing to do so until the appropriate target text is obtained. Because the MT system tends to produce rather literal translations, in order to get the desired output, the original text has to be modified to make it more like the target text. This, as he points out, is of course the reverse of normal student behavior, producing incorrect L2 that too much resembles L1. Richmond calls this "doing it backwards," and the pedagogic reasoning behind this is that it causes the student to focus on the differences between the languages. The method has the advantage that "there is no danger that they will reinforce their own target-language errors" (p. 75), and a further pedagogical aspect of the exercise is that the

“strange and often humorous” L1 constructions produced by the students help to fix the correct L2 constructions in their minds.

This idea of “pre-editing” the input text, i.e., taking a given text and changing it so as to cause some effect in the resulting translation, is also suggested by French (1991) as a way of getting students to appreciate what might be potentially ambiguous in the source text in order to spot the type of linguistic difficulty MT faces.

Shei (2002) suggests that pre-editing can be done both with L1 text and with L2 text, either the student’s own, or a given (native speaker’s) text. Shei has experimented with various approaches for Chinese and English, which have the additional interest of being typologically highly dissimilar. His comments on the L1 pre-editing task suggest that its benefits are rather general, inviting students to “reflect . . . on their knowledge in the target language” (p. 93). Editing native-quality L2 text to coerce a better translation is a controversial approach. Shei reports that some students found the task useful, but others were more negative, suggesting that the exercise only reveals how translating is not a good way to learn the L2, or how poor the student’s L2 grammatical competence was.

Evaluation and Post-Editing of MT Output

Moving away from MT as a bad model, some pedagogical uses of MT can more closely reflect real-life use of this tool. A combination of evaluation and post-editing (i.e., correcting the MT output) has been suggested by various writers.

Belam (2002) describes MT output evaluation exercises with language learners. Students are asked to compare alternative translations which may have been produced by humans or MT systems. She outlines a number of benefits, in particular in focusing on the question of the wider context in which translations are done, but as a language-learning exercise, she returns to the question of exposing students to L2 texts of varying quality. Evaluation work, as well as exposing students to possibly incorrect models, assumes that they are competent to give a relative judgment about translation quality, a recurring difficulty with using MT into the L2.

Post-editing MT output is seen as a useful pedagogical exercise not just because of its applicability in the real world, but because it serves to heighten learners’ awareness of the subtleties of the languages involved. One of the earliest advocates of this approach, French (1991) highlighted the need for students to be self-critical toward their written productions. Belam (2003) describes teaching of post-editing skills to advanced learners, and argues that the activity forces students to study the text in detail and promotes the learning of new vocabulary and expressions, new grammatical points and stylistic features. “Far from confusing students or giving them bad habits, the post-editing exercise can actually be seen to have positive benefits for their language learning” (Belam, 2003, p. 4). Kliffer (2005) reports using post-editing in his language classes with advanced learners. Although stronger students were frustrated by MT’s “stupid” errors, weaker students found evaluating a translation and correcting its mistakes to be less stressful than doing a translation entirely by themselves.

Niño (2004, 2008) reports on a number of experiments in which advanced learners engage in post-editing MT output in the L2. She reports that the skill of detecting and eventually correcting errors is highly linked to the students’ command of the L2, though she recommends this only for advanced students.

Translation Tools in the Classroom

Besides using MT output, some researchers report use of other translation tools. Corness (1985, 1988) gives details of the use of ALPS’s interactive MT system with advanced

learners of German. One of the features of this (now obsolete) system was its “interactive translation” mode, in which it would ask the user to choose among alternative interpretations of an ambiguous phrase. For example, is a *big computer user* a user of big computers or a big user of computers? Corness exploited this facet of heightening awareness of varieties of possible translation which may be due to differences in interpretation, or stylistic differences.

Lewis (1997) devised a course exploiting the fact that MT software often allows users to expand and enhance the system dictionaries, and found that students increased their knowledge of L2 grammar in this way. In particular, students whose command of formal grammar was weak found the MT dictionaries appeared to provide a stimulus for researching areas of grammatical structure.

Away from MT systems themselves, one translation tool worth mentioning is the Translation Memory System (TMS), widely used software which allows users to access previously completed translations when translating a new text, and the related bilingual concordance (Huet, Bourdaillet, & Langlais, 2009), a parallel text indexed by key words in either language. In the case of the TMS, the software looks in the database for a close match to the input sentence, which may differ from it by a few words. It is then up to the translator to decide what to do with the proposed partial match. DeCesaris (1995) suggests that this type of program can be adapted for use in a classroom setting, in which the TMS can be used as a self-learning resource to provide students with immediate access to models that they know are correct. From a language-teaching perspective, this kind of software can serve as a nice alternative to the traditional gap-filling exercise. Shei & Pain (2001) make what amounts to a similar proposal (although they describe it in terms of an MT system based on “lexicalized sentence stems” rather than a TMS).

Somers (2003b) discusses the pedagogic use of a range of language technology tools specifically for teaching Japanese, including MT, but mentioning also text input, speech output, and lexical tools. The particular difficulties that Japanese presents to learners (especially due to typological differences and also the writing system) and the generally good quality of Japanese language technology make this a particularly promising area.

MT for Nonspecialists

So far we have concentrated on the use of MT as a tool for language learners who are in some sense language specialists. There is also a great potential for the use of MT in specialized courses in reading foreign languages for students of other disciplines, e.g., German for scientists, Russian for international affairs specialists, Chinese for business studies, etc. Free Web-based MT can play a massive role in this, an application really well suited to its capabilities. As mentioned above, the quality of state-of-the-art MT is such that it is best suited (if the quality of the input text cannot be limited and controlled) for the purposes of “assimilation,” i.e., providing a rough translation that gives a “gist” of the original text. This may be entirely adequate for nonlinguist users who are specialists in their own fields.

Once this idea catches on, it is quite possible that institutions of higher learning will redefine their foreign-language graduate reading requirements to include, besides proficiency with or without a dictionary, use of MT, whether the free online version or software purchased and installed locally.

Many of the ideas reported above predate the era of inexpensive MT software, including free online MT. Since MT is now available at virtually no cost, we can expect language teachers to be much more willing to experiment with some of these ideas. But this introduces a danger which we address in the final section.

Online MT and the Risk of Plagiarism by Language Learners

As mentioned above, MT is available not only in the form of commercially available software, but also, increasingly, free online. Only a few years after it became available in this form (Gaspari & Hutchins, 2007), Web sites offering translations had become almost innumerable. That the availability of free online MT could pose a problem for language teachers is recognized by McCarthy (2004). As he suggests, there is a danger of students simply feeding the text they have been given as an assignment through the MT system and submitting the output for assessment. McCarthy discusses the reasons why this is bad: it is unfair to students who have invested the intellectual effort and time into producing an original translation, a translation produced with no intellectual input has no instructional value, and it is therefore a waste of the teacher's time to correct it. McCarthy goes on to report a discussion with his students about strategies for combating use of free online MT, and in particular how to penalize it. Somers, Gaspari, and Niño (2006) report a number of methods of successfully detecting what is effectively a special kind of plagiarism, a problem made interesting by the similarity, or otherwise, between the kinds of mistakes a language learner makes, compared to those that an MT system typically makes. Niño (2009) discusses the problem in more detail, covering linguistic strengths and weaknesses of free online MT systems, pros and cons of student use of MT, and suggesting some good and bad examples of possible use of free online MT in the classroom.

There is an irony in that MT is most useful in the classroom when it goes wrong. Successful translations are of limited interest to the learner, but bad translations can be instructive to highlight differences between languages, to illustrate how and to what extent MT works, and, in the teaching of translation as a skill in itself, to focus on choices and dilemmas facing the translator. As the quality of MT improves, so its use in the classroom may widen.

Computer-Assisted Language Learning Effectiveness Research

CAROL A. CHAPELLE

It seems like a simple enough question: Is computer-assisted language learning effective for language learning? Indeed, researchers address this question in a variety of ways, but most language teachers and researchers would point out that the question is considerably more complex than it first appears.

The Complexity of Effectiveness

Complexity lies just beneath the surface of each part of the question. Computer-assisted language learning (CALL) encompasses a wide variety of practices. CALL can refer to such practices as using a vocabulary Web site to engage in self-study of relevant vocabulary during a semester-long reading class. CALL could also refer to use of a multimedia program to give interactive listening practice over the course of five weeks in a listening class. It could mean regular use of computer-generated feedback on grammatical errors in a semester-long writing class, or it could mean a single Internet collaboration with a speaker of the target language in a class in another country. These are just a few examples of what CALL can mean, and the list gets longer as new technologies become available and pedagogies are developed.

The diversity of practices encompassing CALL suggests that the meaning of *effective* will have to be at least equally varied. If something is effective, it produces a desired result, but with such an array of CALL practices, the desired results are many, as well. The result-orientation of effectiveness creates a challenge for those attempting to respond to the question. In the four examples of CALL given above, to claim that CALL had been effective, it would be necessary to show successful outcomes relative to the aims of the learning tasks, i.e., increased vocabulary ability, improved listening skills, improved grammatical competence in writing and increased intercultural competence.

Each of these refers to an aspect of language learning, but how can language learning actually be measured in a way that is valid in a research study? Can the researcher use a score on a vocabulary size test, the score on a standardized listening test, the teacher's judgment of grammatical accuracy on a student's written work, or a score on a measure of intercultural competence? All of these types of assessments might provide some evidence about language learning if viewed relative to an assessment at an earlier time. But it is not entirely clear that each of these could be considered valid for making a claim about the effectiveness of CALL.

In each of the examples, it would be necessary to examine precisely what the learning goals are that pertain to the technology. If in the first case the learners are to select the vocabulary for self-study, it is not clear that the CALL activity should affect overall vocabulary size as measured by a general vocabulary test. In the second case, would listening ability be expected to increase in a manner and to a degree that would be detectable on a standardized test? In the third case, is the learner's use of the grammar correction feedback

intended to teach the grammar, or is the aim to provide assistance in producing the texts in the writing class? In the fourth, what precisely is the learner to gain from one cross-cultural encounter? Each example shows that to investigate effectiveness, the researcher would need a precise and relevant definition of language learning. The definition would need to pertain to the language abilities that the learners were intended to develop as a result of working with the technology. The results would prudently be applied only to the particular aspect of language that was tested. In other words, the research would not allow for making general claims about CALL effectiveness. Instead, researchers would investigate the quality of CALL in a more piecemeal fashion using a number of methodologies, many of which do not rely on an outcome measure.

Effectiveness Relative to Alternative Types of Instruction

Some researchers have investigated claims about the effectiveness of technology relative to classroom instruction. If the question is posed in this relative sense, the issue is to measure the differences in outcomes between two groups of learners. In other words, who learns the vocabulary better: the class that is instructed through CALL allowing for individual collection and testing of the words, or those who are left with paper and pencil tools? Researchers have investigated many aspects of CALL using this approach, including grammar, vocabulary, reading, writing, and listening communication skills, and overall learning. Grgurovic (2007) provided a searchable database where readers can explore these studies. A look at Grgurovic's (2007) summary of the results does not suggest a definitive answer to the questions about CALL effectiveness relative to other forms of instruction. However, it reveals many studies in which results favor the CALL group. When the studies found in this systematic search of the second/foreign-language learning research were further analyzed through a meta-analysis (see Norris & Ortega, 2006), the overall finding was that for studies conducted with methodological rigor, the CALL groups performed systematically better than their counterparts who did not use CALL. The mean differences were small, but statistically significant (Grgurovic, Chapelle, & Shelley, 2011).

As Felix (2005a, 2005b) points out, however, such comparative studies and their derivative meta-analyses are limited in the nature of the results they can provide. Such studies lack important information needed to understand the conditions under which CALL is successful. Cobb (1997) argues that such an understanding and theorizing of the conditions is essential if researchers are to make sense of the research results. The "black box" of the technology condition has been an ongoing criticism of such research for many years (Pederson, 1987; Dunkel, 1991; Chapelle, 2001). As a consequence, many researchers have used other methods to attempt to gain more detailed information about where, when, why, and with whom CALL is effective.

Getting at the Detail

Researchers studying the effectiveness of classroom teaching recognized long ago that comparisons of outcomes alone were inadequate as scientific evidence for conclusions about the superiority of one method over another for language learning (e.g., Chaudron, 1988). Similarly, researchers studying CALL would like to be able to make claims about the quality of particular learning activities for developing specific aspects of communicative language ability as well as to produce findings that can be used to improve the design of activities for learners. Five examples help to illustrate the types of research that are addressing questions about the nature and quality of the experience that students engage in as they work on CALL.

First, researchers examine learners' use of negotiation strategies as they seek to understand meaning while they work on CALL. Based on theoretical and methodological principles coming from interactionist research on second language acquisition (Pica, 1994), these researchers have used interaction analysis of human-computer interaction or focused discourse analysis of recorded written and oral conversation to analyze the quality of the interactions that learners engage in during the CALL activity. Findings from studies of human-computer interaction have been positive overall: Students who interact with the program to obtain help as intended do tend to learn (e.g., Plass, Chun, Mayer, & Leutner, 1998). Research investigating students' language as they communicate with each other online has found that if activities are designed carefully, students do indeed use negotiation of meaning strategies which are thought to be beneficial for language development. When written interactive communication is involved, negotiation of meaning can be accomplished in a number of different ways; moreover, students have also been observed to engage in negotiation of form, which suggests that metalinguistic awareness is prompted by the activity (Pellettieri, 2000). Overall, the research supports the claim that students' interactive written communication in well-designed activities results in students' reflection on language and self-correction during conversation.

Sometimes, in combination with the first approach, a second approach to investigating CALL examines learners' development of specific linguistic features that are used while working on CALL. One type of study investigates activities aiming to teach students particular linguistic features—most typically vocabulary—and interaction pertaining to the learning targets is documented. In such a study, outcomes can be tested because linguistic features are targeted (Smith, 2004). In another type of study, learners' language is observed and documented as they work on activities online over the course of several weeks or a semester. Progress is noted through documentation of changes in the learners' language as it develops throughout the activities (Belz, 2003). This methodology has been used to examine grammatical and pragmatic aspects of the learners' language. Belz and Kinginger (2003) note that intercultural collaborations with peers afford opportunities for learners to develop pragmatic competence, so the research aims to support this claim with findings about pragmatic development.

A third focus of investigation is the interaction that students engage in, which may be relevant for their development of intercultural competence. In particular, research has examined miscommunication that may occur as a result of students' limited intercultural abilities. Analysis of such interaction suggests that when a culturally based misunderstanding has occurred, recovery is not a given (Ware & Kramsch, 2005). Unlike linguistic breakdowns that spawn negotiation of meaning, culturally based breakdowns seem to be very difficult to repair, and it is not evident that learners gain cultural understanding from such breakdowns. This is an important area of study for teachers and researchers wishing to claim that cross-cultural collaborations over the Internet help to develop intercultural competence.

A fourth approach is to investigate stakeholders' perspectives on the quality of their experience when working with CALL. Particular questions can be devised to investigate users' perceptions relative to claims that materials developers make. The stakeholders are typically the teachers and students who use the materials. One such study investigated *Longman English Interactive* (Rost & Fuchs, 2004), a video-based multimedia program aimed at developing the integrated language skills of beginners to intermediate learners (Jamieson & Chapelle, 2010). The basis of the evaluation was a set of six criteria from theory and research in instructed SLA (language-learning potential, meaning focus, learner fit, authenticity, impact, and practicality), as outlined by Chapelle (2001). Opinions pertaining to these criteria were solicited at multiple points in time through a survey of over two hundred students in the United States and three countries outside North America. Quantitative

results, for the group as a whole as well as for the students and teachers at each location, revealed that positive claims about the six criteria could be justified for the whole group, but that not all claims were supported for all locations. In other words, the context affected the evaluation of the CALL materials.

A fifth approach to research is undertaken in view of the recognition that results in all of these studies appear to be affected in part by factors that occur prior to and in the institutional context surrounding the activities under investigation. Students' own goals for language learning, as well as their experience with and interest in technology, undoubtedly influence the success of activities introduced by teachers (Warschauer, 1999). Factors in students' prior lives affect their perceptions of technology possibilities, which in turn have implications for their learning through technology (Thorne, 2003). If the claims to be made about CALL take into account learners' background, motivation, interests, knowledge, and access to technology, as some argue they should, researchers typically use qualitative research methods such as case studies to capture a detailed understanding of the individuals (Duff, 2008). Moreover, language programs and institutional decision making also affect what, how, and when technology is used for language learning (Burston, 2006).

Conclusion

The research that is done to investigate CALL demonstrates that statements about effectiveness of outcomes measured by tests do not encompass all the types of claims researchers want to make about CALL. Instead, researchers hope to make a range of assertions about the quality of interactions, acquisition of particular linguistic features, benefits of intercultural encounters, and users' opinions about specific aspects of the activities. Such claims vary according to the audience for the research results (Chapelle, 2007). Particularly for those in applied linguistics, the idea that technology could be categorically effective or ineffective does not sit well with professional knowledge about the many facets of language learning and the context-specificity of the learners' needs. Rather than seeking evidence about a monolithic technology effect, applied linguists tend to study a range of factors in the learning situation in detail using a variety of research methods.

Computer-Assisted Qualitative Data Analysis Software (CAQDAS)

JEREMIE SEROR

In seeking out techniques and guidelines best suited to conduct qualitative research, researchers are increasingly turning to the growing availability of computer software packages designed for qualitative research and data analysis. Also known as CAQDAS (computer assisted qualitative data analysis software), these computer programs produced to facilitate qualitative researchers' analytical work first appeared in the early 1990s (Basset, 2004). Nevertheless, to date, discussions in the literature of the adoption and impact of these digital tools by researchers remain limited when compared to the much-better-established role of computer software for quantitative data analysis (Lewins & Silver, 2007). This may well be about to change as the list of available software programs and their professional commercialization as widely available tools has increased steadily. Some of the original CAQDAS programs such as ATLAS.ti, NVivo, and HyperResearch are now joined by a wide assortment of programs whose variety of functions and capabilities reflect the broad range of methods associated with qualitative inquiry. Nowadays, for instance, qualitative researchers may choose from programs specifically designed for the analysis of audiovisual data (e.g., Transana) or from mixed methods programs focusing on text retrieval and the integration of statistical tools to integrate content analysis and text mining dimensions (e.g., QDA Miner).

Although each package offers a unique set of tools and interfaces, all take advantage of technological innovations in the area of digital data management to assist and enhance the way researchers store, edit, retrieve, link, and visualize complex and varied data formats, including the "unstructured" data that is so often at the heart of qualitative research (Bazeley, 2008).

While not without controversies (see more on this below), researchers who have examined the use of CAQDAS increasingly highlight the potential these packages have to change how researchers interact with qualitative data and how, with reflective and appropriate use, the software can augment the flexibility, efficiency, and rigor of the analytical process (Lewins & Silver, 2007).

From its very first versions, crucial to the design of CAQDAS was a transition from the hands-on work of annotating, cutting up, filing, and searching for data in stacks of papers to an electronic environment where these tasks could be executed digitally on a computer screen. Thus, whereas the essential functions of CAQDAS echo processes traditionally associated with qualitative data analysis, the computer environment simplifies and speeds up the reiterative process of examining, storing, coding, organizing, and recording thoughts while sifting through the data to test ideas and theories.

For instance, the time-consuming process of coding data segments and (re)organizing them in both hierarchical and nonlinear structures is greatly simplified by CAQDAS packages that allow, for example, a researcher to code a section of an interview by simply selecting and dragging on their screen a segment of an interview onto the label of a relevant analytical theme. Clicking another button allows a researcher to link a memo capturing his or her thoughts about this segment or to bring up a list of all themes currently associated with that interview. Another click displays how many of these themes are also "coded"

in interviews with other participants, allowing for cross-case comparisons. Finally, clicking on any of these themes produces a list of all the data sources (specific quotes, whole documents, images, audiovisual segments, or all of these) ever linked to this theme, each of which can in turn be instantaneously called up for review and further analysis and coding.

CAQDAS designers have also taken advantage of computers' automated record-keeping to assist the process of tracking, updating, or undoing analytical steps. In this way, qualitative analysis is rendered more efficient, and researchers are offered an increased sense of flexibility and capacity for risk taking with their analysis (Weitzman, 2003) while producing "a strong record of transparent and replicable research" (Cousins & McIntosh, 2005, p. 592), which helps enhance the thoroughness and rigor achieved by qualitative researchers (Lu & Shulman, 2008).

Beyond the speed and ease offered by these programs, for many users, the true attraction of these tools lies in CAQDAS's capacity for experienced users to integrate a degree of complexity and detail into their analysis that would be difficult to achieve without computers (Richards, 2002). Part of this is rooted in the improved sense of efficiency and overall organization offered by CAQDAS programs, which locate all data sources and analytical work within a single, uniform, searchable file or folder that can in most cases be stored and transported on a USB memory stick (Lu & Shulman, 2008).

Researchers working with CAQDAS have also noted the enhanced capacity to work with large data sets (Lu & Shulman, 2008), and the ability to explore data visually through the innovative and dynamic graphical representations and modeling systems which are now a common feature of most CAQDAS (Parmeggiani, 2009). There are also considerable advantages linked to computers' capabilities of establishing and examining links between various data components. In particular, opening up new possibilities beyond a traditional code-and-retrieve approach, hypertext links, frequency counts, Boolean searches, automatic coding, and cross-matching of coded data with case descriptions are now frequently part of sophisticated search functions available to users to explore patterns in their data.

Perhaps most important in transforming what CAQDAS packages might offer researchers has been the capacity for these programs in recent years to import and manipulate an ever-widening range of data sources. No longer are researchers limited to working with simple text files. Many packages can now easily integrate rich text documents, as well as multimedia files such as film, audio, and images. The latest version of Atlas.ti at the time of writing, for example, allows researchers to work directly with PDF files and add geographical location tags to documents imported into a project through an embedded Google Earth function.

Through this expanded capacity to work with multiple forms of data within the programs themselves, researchers are now freer to move back and forth from raw data (full transcripts, pictures, audio recordings, etc.) to analytical categories, to theory building as part of a "context-rich" analytical process (Lu & Shulman, 2008). In the field of applied linguistics, where working with discourse frequently requires considering both the micro and macro contexts in which language is embedded (Duff, 2007), this ability to switch effortlessly from the actual recordings of language events to analytical constructs is particularly interesting. At any time, findings emerging from the analysis can easily be traced back to specific sections of raw data, which can in turn easily be resituated within a larger context, all while tracking and annotating the analytical steps that helped identify these sections as relevant. This offers considerable benefits for researchers seeking to enhance the verifiability of their work, while rebutting popular criticisms of qualitative research as relying too often on arbitrarily chosen quotes (Antaki, Billig, Edwards, & Potter, 2003).

Illustrating a trend toward the adoption of CAQDAS for discourse analysis, King (2010), for example, reports making successful use of NVivo's ability to code, link, and later merge

various explorations of his data, to explore membership categorizations found in young participants' discussions of the impact of a year-long break prior to beginning university studies. Mavrou, Douglas, and Lewis (2007) similarly report on their use of Transana to work with multiple levels of transcriptions, all synchronized with raw video recordings, to conduct a fine-grained analysis of interactions and exchanges between "able" and "disabled" students in inclusive classrooms.

Another important innovation in the use of CAQDAS has been the emergence of features designed to facilitate team-based research, with multiple researchers collaborating and working on a single qualitative project (Bazeley, 2008). A number of CAQDAS programs offer merging functions for collaborative work, as well as cross-rater verification functions that can be used to confirm the degree of agreement in the interpretation of data by team members. NVivo's latest release at the time of writing permits team members to work at a distance on a single server-hosted project.

Finally, CAQDAS's facilities for the management of complex data have been seen with great interest by researchers interested in mixed methods projects that combine qualitative techniques with quantitative tools. CAQDAS packages such as NVivo and MAXqda feature the ability to import tabular data from spreadsheet programs, to add depth and richness to the descriptions and analysis of participants or cases found in a study (Johnston, 2006).

Despite what this software has to offer, the growing popularization of CAQDAS for qualitative research has not been without contention. Concerns have been raised about the potential negative impact that computer-based interfaces can have on the quality of data analysis possible in an electronic environment. For Mangabeira, Lee, and Fielding (2004), it is a question of realizing that not all researchers will have the experience, comfort level, personal inclination, or all of these to work effectively with computers for the organization of qualitative data analysis and its workflow. Indeed, rather than simplifying the analysis, for some, on-screen interfaces simply entail the need to relearn to do "digitally" what might otherwise be achieved with little thought (if perhaps more slowly) in a more analog fashion. Richards (2002) further warns that the software's representation of data in digital windows, as partitioned segments separate from the whole, with particular fonts, formats, and limited visual ranges, can decontextualize and possibly distance researchers from their original data. Echoing this necessity to question the imposed limits of a digital workspace, MacMillan (2005), in her review of the efficacy of CAQDAS for discourse analysis, questioned whether software could ever offer the degree of organization required for the detailed work entailed by discursive analysis, and deplored the effort required to adapt one's analysis to what she perceived as an overall structural emphasis on code-and-retrieve processes and a grounded theory approach to qualitative data analysis.

Finally, unease has been expressed at attempts to take advantage of computers' capacity to work with larger sample sizes while integrating quantitative techniques into qualitative projects. Some see in these trends, and in their implied change in focus from the meaning found in data to frequency counts, a dangerous shift away from the qualitative inquiry tradition's deliberate focus on the unquantifiable and on smaller data sets (St John & Johnson, 2000).

While the above concerns do need to be taken into consideration by researchers contemplating the adoption of CAQDAS, it would be simplistic to state that it is the programs themselves, rather than *who* uses them and *how*, that should be examined when determining the potential contribution of these tools to qualitative research. Richards (2002) calls for more frequent and detailed assessments of what is actually done with these tools rather than simply a critique of their capabilities (see Mavrou et al., 2007, for a good example of the insights to be gained from this type of work). In fact, experienced researchers will recognize that these new tools are in this sense no different from any of the more traditional methodological tools at their disposal. Whether it be choosing to work with a CAQDAS

package or deciding on a specific transcription convention to use when working with interviews, the best approach will be to keep in mind that the value of these tools will unavoidably be linked to researchers' needs in terms of resources, methodology, and goals as well as their personal preferences, experience, comfort levels, and willingness to research and to train themselves with these tools.

In light of the fact that CAQDAS programs come with a technical and methodological learning curve (Johnston, 2006), Lewins and Silver (2009) suggest this reflection process is especially important when choosing a package. On the basis of their own comparisons of various available CAQDAS programs, they stress that although most users would like a simple answer to the question "Which is the best package?" this is in fact impossible. While most programs offer the same basic features, the differences which set them apart in the way these features are accessed and realized will mean that each package will be best suited for specific types of projects and researchers. As such, it is the users who take the time to inform themselves well about CAQDAS and what each program has to offer who are likely "to find the most satisfying fit between these tools and their own research needs" (Cousins & McIntosh, 2005, p. 596).

A growing body of work suggests that researchers in a wide range of disciplines including the natural sciences, business, and creative arts are taking the time to make use of CAQDAS (Bazeley, 2007). This interest is matched by an increased demand for training with CAQDAS and suggests these researchers, including applied linguists, have found ways to take advantage of this software to support and add to their work, exploring the complexities and nuances that characterize the richness of qualitative data. This body of work also demonstrates that CAQDAS will likely continue to play a significant role in the legitimization of qualitative research as an important and valid mode of inquiry, as its user base moves from early adopters to a growing number of mainstream users (Fielding & Lee, 2002). Indeed, if, as suggested by Atkinson, Coffey, and Delamont (2001, p. 15), "we are only just beginning to witness the impact of information technology on qualitative research," even those uninterested in moving away from more traditional approaches to qualitative data analysis may find it useful to at least consider how these new tools are set to change, transform, and shape the future of qualitative research, if not in their own work, then in the work of a future generation of researchers.

Computer-Assisted Translation

KEIRAN J. DUNNE

Computer-assisted translation (CAT), sometimes called computer-aided translation or machine-aided translation, is the process whereby a human translator is assisted by specialized software. The defining characteristic of CAT is that the software *helps* the translator, who retains control over the translation process, unlike machine translation (MT), in which software actually *replaces* the translator.

CAT and MT represent two different approaches to the question of how to use computers to produce better, quicker, and cheaper translations. Early efforts sought to fully automate translation using MT. In the 1950s, research groups were formed at a number of universities across the United States. Encouraged by early demonstrations of the practical feasibility of machine translation, particularly the 1954 demonstration by a joint IBM–Georgetown University research team, US government agencies invested significant amounts of money in MT research (Hutchins, 1978).

However, it soon became evident that researchers had underestimated the challenges of MT. The resulting translations were rudimentary and often nearly incomprehensible, and critics began to question the utility of MT (Hutchins, 1978). Yehoshua Bar-Hillel (1960, pp. 158–63), for instance, argued that fully automatic high-quality translation (FAHQT) was a dream that would not be achieved in the foreseeable future, if ever. In Bar-Hillel's view, the challenges of MT stemmed not from translation, but from comprehension. If a computer cannot determine the meaning of ambiguous words or sentences, he reasoned, then practical MT would require human postediting to correct the (mis)translations, in which case the process could not truly be characterized as FAHQT. Bar-Hillel (1960) asked whether postediting was the best use of human labor in the translation process. Instead of attempting to supply computers with encyclopedic knowledge and program them to make human-like inferences when facing ambiguity, ideas he dismissed as “utterly chimerical” (p. 160), Bar-Hillel argued that researchers should concentrate on developing practical machine aids to translation, which would be far more feasible than achieving FAHQT.

In 1964, the Automatic Language Processing Advisory Committee (ALPAC) was formed to evaluate the relative usefulness and promise of research and development in the field of automated foreign-language translation on behalf of several US government agencies. The committee's report observed that no existing system performed true “machine” translation, as the production of useful output from state-of-the-art systems required human postediting (ALPAC, 1966). MT was also deemed to be less accurate, slower, and harder to understand than human translation, a dire assessment given the stated imperatives of improving quality and speed while decreasing cost. Echoing Bar-Hillel, the committee's verdict was unequivocal: “We do not have useful machine translation. Further, there is no immediate or predictable prospect of useful machine translation” (ALPAC, 1966, p. 32). The report concluded that machine aids to translation might be a fruitful means to achieve better, quicker, and cheaper translations.

Due largely to the ALPAC report, MT research fell into disrepute and attention turned to the development of translation aids (Hutchins, 1998a; 1998b). Early efforts focused on lexicography and terminology, reflecting the fact that translators of scientific and technical

2 COMPUTER-ASSISTED TRANSLATION

texts typically spent more than half of their time researching the translations of technical terms (ALPAC, 1966, p. 27; Zachary, 1979, p. 19). Indeed, the first lexically oriented translation aids predate the ALPAC report: the Terminological Bureau of the European Coal and Steel Community created its automatic phrasal dictionary, DICAUTOM, in 1963; two years later, the West German Federal Office of Languages implemented LEXIS, a computerized system that enabled the creation of text-oriented glossaries, i.e., lists of terms that appeared in a given source text along with their approved translations (Hutchins, 1978). The 1970s witnessed the development of electronic term banks, such as EURODICAUTOM, the terminology data bank for the translation services of the European Community, and TERMIUM, which was created at the University of Montreal in 1970 as a centralized terminology storehouse for Canada's translation services (Hutchins, 1978).

Building upon these efforts, researchers expanded the conceptual framework of CAT during the 1970s and 1980s. Thus, Friedrich Krollmann (1971, pp. 118–19) proposed expanding the terminological database into a “linguistic data bank” comprising seven interlinked subbanks:

1. Multilingual dictionaries for lexicography;
2. Multilingual dictionaries for machine-aided translation;
3. Monolingual dictionaries containing additional information on lexicographical entries, particularly definitions;
4. Thesauri for information retrieval/documentation;
5. An index for registering and checking translations, to avoid duplication;
6. A text corpus bank for linguistic analyses;
7. Translation archives.

This linguistic data bank would be accessible not only to translators, but also to lexicographers and other multilingual information workers over a network. Although the state and cost of the technology precluded development of such a system at the time, Krollmann's model represents an early prototype of an enterprise computer-assisted authoring and translation system.

Krollmann's proposals for a translation index, corpus, and archive of translated text were adopted and expanded upon by Peter Arthern in 1979. Observing that many European Community texts requiring translation were quite repetitive and reproduced extensive passages from other documents, Arthern argued that translators were wasting considerable amounts of time duplicating previous translation work. To solve this problem, he proposed a computer-based system of “translation by text-retrieval” (Arthern, 1979, p. 93) whereby the organization would store all texts along with the corresponding translations in a centralized repository, so that users could locate any given passage of text in any of the organization's working languages, along with the corresponding translation(s). Translation would involve comparison of new text to previously translated texts, most likely one sentence at a time, followed by retrieval and printing of the nearest available equivalents for subsequent reuse. This concept of sentence-level translation storage and reuse, now commonly known as “translation memory” (TM), would not be widely implemented until the 1990s. Arthern also noted that his proposed system could easily be supplemented by adding MT capability.

In 1980, Martin Kay published his seminal report, *The Proper Place of Men and Machines in Language Translation*, in which he proposed a translator's amanuensis, or workstation, as an answer to the question of how—and to what extent—machines should be used in translation. The amanuensis envisioned by Kay would incorporate a text editor enabling source-text display in an upper window and simultaneous target-text production in a lower window. Echoing Bar-Hillel and the ALPAC report, Kay (1980) called for the

incorporation of “translation aids” (p. 12) from an editable dictionary to a history function allowing the translator to track decisions made about specific words and phrases so as to systematically control how subsequent occurrences of such difficulties would be treated. This function can be seen as a precursor to future TM implementations.

During the 1980s, Alan Melby (1981, 1982, 1983, 1987) made similar proposals for the development of a CAT system. Having spent the 1970s working on machine translation, Melby (1983) observed that MT “must be almost perfect or it is nearly useless” because postrevision of even 20% of the text negates the cost, quality, and time savings that MT might otherwise achieve (p. 174). Melby thus proposed a three-level system of “translator aids” (1983). Level one would offer a word processor and access to a bilingual dictionary or terminology file. Level two would offer all functions of level one, plus a preprocessing capability to search for unusual words or phrases, automatic lookup of terms in the bilingual terminology file and a means of inserting selected terms from the terminology file into the target text. Finally, level three would offer all functions of levels one and two, plus an interface to a MT system that would enable the translator to consider MT sentences and accept, modify, or reject them one at a time, thereby avoiding the classic “all-or-nothing” MT problem. Like Kay, Melby wanted translators to be able to make their own decisions about when/what to translate or to postedit, and thus to remain in control of the translation process.

Automated Language Processing Systems (ALPS) was the first company to offer translator aids in a commercial product. ALPS’ multilingual word processor offered three levels of support: “a multilingual word processor with on-demand lexical lookup . . . a translation item-oriented editor that automatically matched online source text against dictionaries . . . and a sentence-by-sentence full translation system that interacted with the translator to resolve ambiguities in source language analysis, source-target language transfer, or target-language generation” (Lonsdale, 2007, p. 3). The product also offered a “repetitions-processing” feature, enabling translators to specify the creation of a “repetitions file” into which each segment was copied along with its translation as the translator proceeded through the file. In this way, the translator could compare new source text to segments from previously translated texts, retrieve all matches and reuse them in the current project, thus avoiding the translation of repeated segments of text; this was “clearly an early implementation of basic features of a ‘translation memory’” (Hutchins, 1998a, p. 12).

In 1988, Brian Harris made a major contribution to the concept of translation memory by proposing a new form of translator’s aid, the “bi-text,” defined as “a single text in two dimensions” in which the source and target segments are associated by the act of translation to form translation units (p. 8). Harris envisioned an environment in which translators would store all translation units in the form of bitext. This would enable a translator to search for all sentences in which a given word or phrase occurs and display the corresponding translation units. Harris (1988) proposed that search results encompass not only exact matches but also matches that would be similar enough to be of use to the translator.

By the late 1980s, the notion of translation aids was increasingly familiar to both scholars and practitioners (Vasconcellos, 1988), but translators still viewed them “as something for the future” (Hutchins, 1998a, p. 13). Thanks to the commoditization of the PC and the advent of mass-market desktop software during the 1990s, translation aids have become accessible to individual translators in the form of specialized translation software, commonly referred to as “CAT tools” or “translation tools.” Today, CAT is a *de facto* tool of the trade in commercial translation in many domains, including scientific, technical, medical, and legal translation, as well as localization.

Since its inception in the 1960s, CAT has sought to develop computer-based aids to address specific problems in the translation process. From the 1960s to the 1990s, CAT

focused largely on lexicography, terminology, text processing, and reuse of previously translated material. Over the past decade or so, CAT has explored new ways to support translators, including automated checking of spelling and terminological consistency, automatic suggestion of translation as the user is typing based on similarity to previously translated material, and even optional integration of machine translation. In this respect, computer-assisted translation can be said to have come full circle, nearly five decades after the publication of the devastating ALPAC report.

Historically, CAT has focused on assisting humans as they translate documents. However, the past decade has witnessed a shift from the authoring of documents to the creation of content, the advent of structured (semantic) authoring, and single-source publishing, whereby content is separated from the means of its presentation and assembled on demand in response to a specific user request (Rockley, 2003; Gollner, 2009). These developments present translators with new challenges, especially the comprehension and translation of chunks of text without context. This radical shift in authoring also raises anew the question of how best to use technology to support translation and translators.

Computer-Assisted Vocabulary Load Analysis

STUART WEBB AND PAUL NATION

The development of computer software and frequency-ranked word lists has made it easier to determine the representation and frequency of words in text. It has allowed researchers to collect data on the millions of words in corpora in a matter of seconds. Analysis of the vocabulary in text and corpora can provide data about the ease or difficulty with which discourse may be understood, the extent to which words may be learned through reading and listening, and the words which may be most useful for comprehension.

Research focused on vocabulary load has primarily concentrated on four areas: the vocabulary size necessary to understand different types of discourse, the potential for incidental vocabulary learning through reading and listening, the degree to which words recur in discourse, and the identification of technical vocabulary in text. The following sections will provide an overview of research in each of these areas, describe how to carry out an analysis of vocabulary load, and discuss the limitations of studies analyzing vocabulary load.

How Many Words Do You Need to Know for Comprehension of Written and Spoken Discourse?

Several studies have analyzed different types of discourse to determine the vocabulary size necessary for comprehension. This is useful for teachers and learners because it provides target vocabulary sizes at which discourse may be understood. This line of research builds on empirical studies which have shown that reaching 90–98% coverage (the percentage of known words in a text) may indicate adequate comprehension depending on the modality (listening or reading) and the type of text. It is important to note that coverage figures provide an indication of adequate comprehension rather than ensuring adequate comprehension. You may know all of the words in a text (100% coverage) but that does not mean that you will understand the text. A 95%, 98%, or 100% coverage figure does, however, provide a useful indication of whether or not a text may be understood.

The unit of counting words in these studies is typically the word family. The rationale behind counting with word families is that learners may recognize unknown members of a word family through knowledge of another member of the family. For example, if you know the word *assess*, you may be able to understand the meaning of *assessment* or *reassess* when they are encountered in context. This, however, is likely to depend on the level of the learners. A more appropriate unit of counting might be word types or lemmas for beginners because they would not have the knowledge of word parts necessary to understand related family members.

Laufer (1989) found that 95% coverage could provide reasonable comprehension of a general academic L2 text. Hu and Nation (2000) found that 98% coverage was necessary for adequate unassisted L2 reading comprehension. This was supported by Carver (1994) who found that 98–99% coverage provided adequate L1 comprehension of a text with the necessary coverage being dependent on the difficulty of the text. Bonk (2000) found that

with adequate coping strategies, L2 learners could have adequate L2 aural comprehension of short texts at far below 95% coverage, and Larson and Schmitt (cited by Schmitt, 2008) suggest that 90% coverage may provide adequate listening comprehension. The contrasting results and variability in comprehension between texts and discourse types suggest that more research is needed, although some of the differences can be explained by the definition of comprehension in the studies. What might be defined as adequate comprehension in one study may be something quite different in another study. There is a need for a precise construct of comprehension that will allow comparison across studies.

Nation (2006) analyzed the Wellington Corpus of Spoken New Zealand English (WSC) and found that a vocabulary size of 3,000 word families was necessary to reach 95% coverage, and a vocabulary size of 6,000 to 7,000 word families was necessary to reach 98% coverage of spoken discourse. This was supported by Adolphs and Schmitt's (2003) analysis of the spoken Cambridge and Nottingham Corpus of Discourse in English (CANCODE), which indicated that a vocabulary size of 3,000 word families was needed to reach 95% coverage of spoken discourse. Nation also examined the vocabulary size necessary for comprehension of a graded reader, novels, newspapers, and a children's movie and suggests that a vocabulary size of 6,000–7,000 word families is needed to understand spoken discourse and a vocabulary size of 8,000–9,000 word families is needed to understand written discourse. These figures are based on 98% coverage being necessary for adequate comprehension.

Hirsh and Nation (1992) examined three short novels aimed at teenage or younger readers to determine the coverage of the most frequent 2,000 word families and the vocabulary size necessary to reach 97–98% coverage. They found that a vocabulary size of the most frequent 2,000 word families reached only 90–92%, and a vocabulary size of 5,000 word families reached 97–98% coverage. They suggest that 97–98% coverage may be sufficient for learners to read novels for pleasure.

Webb and Rodgers (2009a, 2009b) analyzed the vocabulary in 88 television programs and 318 movies. They suggest that the presence of visual input together with aural input is likely to facilitate comprehension and that 95% coverage may be sufficient for understanding L2 television and movies. The results showed that coverage is likely to vary between individual programs and movies. Overall, a vocabulary size of 3,000 word families plus proper nouns and marginal words provided 95% coverage of both discourse types. Webb and Rodgers report that once learners have knowledge of the most frequent 3,000 word families, regular viewing may lead to significant incidental vocabulary learning as well as improved comprehension of spoken input.

Future research needs to carefully define adequate comprehension and the conditions under which texts are used in order to get a clear picture of vocabulary goals.

What Is the Potential for Incidental Vocabulary Learning Through Reading and Watching Television and Movies?

Another way to analyze vocabulary load is to look at the frequency of occurrence of the words in a text. This line of research draws on research that has shown that the more words are encountered in context, the more likely they are to be acquired without conscious attention to vocabulary learning (Saragi, Nation, & Meister, 1978; Jenkins, Stein, & Wysocki, 1984; Horst, Cobb, & Meara, 1998; Rott, 1999; Waring & Takaki, 2003; Webb, 2007). Research indicates that from six (Rott, 1999) to 20 encounters (Waring & Takaki, 2003) may be needed to learn words incidentally through reading with the amount of knowledge gained dependent on the contexts in which the words are encountered (Webb, 2008), and the characteristics of the words themselves. Based on these figures, researchers can get some indication of the extent to which words may be learned in a text or corpus.

How Often Do Words Recur in Discourse?

Nation and Wang (1999) examined the potential for vocabulary learning offered by graded readers using a corpus of such readers at various levels. They looked at how often vocabulary recurs at each level to determine the amount of reading necessary to learn the newly introduced items. The results indicated that if learners read seven graded readers in a level they would encounter 40% of the new items 10 or more times.

Webb (2010a) and Webb and Rodgers (2009a) took a similar approach, examining the number of times word families were encountered in television programs and movies. They looked only at word families which were likely to be unknown to viewers—low-frequency items found in Nation's (2006) 4,000–14,000 word lists. Both studies indicated that there would be little to no vocabulary learning through watching a small number of movies or television programs. However, with regular viewing, incidental learning could be substantial.

What Is the Technical Vocabulary of a Text?

Looking at the number of encounters with words in a text may also enable us to identify the technical vocabulary for that topic or text. Technical words are items that are more common in one area than outside of that area. For example, *word*, *grammar*, *lemma*, and *morpheme* are technical words in applied linguistics because they are encountered with greater frequency in applied linguistics than in other areas such as physics and medicine. Identifying the technical vocabulary is useful because it sheds light on the low-frequency words which may be of greatest value to learners with specific academic purposes. In this approach to analysis of vocabulary, it is important to have a significant number of running words in a text to clarify what is and what is not technical vocabulary.

Ward (1999) identified the most frequently occurring words in an engineering corpus and then examined the coverage which this corpus-derived vocabulary (which included high-frequency, academic, and technical words) would provide in an independent set of engineering texts. His results indicated that the most frequent 2,000 words in the corpus provided over 95% coverage of the texts. Chung and Nation (2003) analyzed the vocabulary in an anatomy text and an applied linguistics text using a corpus-comparison approach to identify the technical vocabulary. They identified 4,270 of the word types in the anatomy text (37.6%) and 835 of the word types in the applied linguistics text (16.3%) as technical. The study indicated that a large percentage of words may be unique to a specialist domain and that the number and percentage of technical words and types of technical words are likely to differ between subjects.

Another reason to look at the most frequent words in a text is to determine the value of preteaching or glossing those words. Webb (2010b) examined the vocabulary in television programs to determine the extent to which knowing the 10 most frequent word families outside the high-frequency general service vocabulary would increase coverage. The study indicated that prelearning topical vocabulary may be a useful method of increasing comprehension. Webb (2010c) took a similar approach, creating glossaries of the most useful words in related television programs. Identifying a learnable number of topic-related words may provide learners with a means to reduce the vocabulary load of discourse.

How Does Vocabulary Differ in Related and Unrelated Discourse?

Comparing the vocabulary in different texts can provide some indication of the ease with which these texts may be understood as well as the potential for vocabulary learning

through reading or listening. Several studies have looked at the number of word types and families in related and unrelated discourse as well as the frequency of occurrence of those items. It is important to compare texts with an equivalent number of running words to make a valid comparison between texts. This line of research has been useful because it shows the benefits of narrow reading and listening; reading or listening to discourse about a single topic or related topics can reduce the lexical demands of the task and increase the potential for learning the vocabulary that is encountered.

Hwang and Nation (1989) compared the vocabulary in running news stories and unrelated news stories. They found that words outside the most frequent 2,000 word families were more likely to recur in the running news stories than in the unrelated news stories. Because research has shown that increasing the number of encounters with words in context is likely to increase their potential for learning (Saragi, Nation, & Meister, 1978; Jenkins, Stein, & Wysocki, 1984; Horst, Cobb, & Meara, 1998; Rott, 1999; Waring & Takaki, 2003; Webb, 2007), the study indicated that there was greater potential for incidental learning in related text. Sutarsyah, Nation, and Kennedy (1994) looked at the vocabulary in an economics text and the vocabulary from a collection of short academic texts on a variety of topics. They found that the economics text contained a much smaller number of word types (9,469) and word families (5,438) than the academic texts (12,744 and 21,399 respectively), and the number of times the topic-related words in the economics text were encountered was higher in the economics text than in the collection. Schmitt and Carter (2000) also compared the vocabulary in related and unrelated sets of newspaper articles. They found that the newspaper stories with related themes used fewer word types than the unrelated articles and that content words recurred more often in the related articles than in the unrelated articles.

Gardner (2008) looked at the vocabulary in fifth-grade and sixth-grade expository and narrative texts with similar and unrelated topics. He used a slightly different approach from the other studies. He examined the number of times word types recurred rather than word families and included proper nouns in his totals. He found that words were more likely to recur in expository texts than in narrative texts.

Rodgers and Webb (in press) examined the vocabulary in related and unrelated television programs. They looked at all of the episodes in a complete season of six different programs and compared each one with a set of unrelated programs. The results showed that there were fewer word families and word types, and that low-frequency words recurred more often in the related programs than in the unrelated programs. Taken together, the research indicates that related texts may have a lighter vocabulary load than unrelated texts and that there is greater potential for vocabulary learning through reading texts or watching television programs with related topics.

How Do You Carry Out an Analysis of Vocabulary Load?

Carrying out an analysis of the vocabulary in text can be a relatively straightforward procedure. We will discuss it using the RANGE program (Nation & Heatley, 2002) because it is the most commonly used software in studies of vocabulary load. RANGE allows users to find the number of words necessary for comprehension, determine the number of encounters with word types and families, and see the range of use of vocabulary in multiple texts. It also provides data on the tokens, types, and word families according to the word lists that are used in the analysis. RANGE can be used with the supplied word lists (1,000- and 2,000-word lists based on the General Service List (West, 1953), the Academic Word List (Coxhead, 2000), or Nation's 14 British National Corpus (BNC) 1,000-word lists), or researchers can use their own word lists with the program. It is freeware and available from Paul Nation's Web site: <http://www.victoria.ac.nz/lals/staff/paul-nation/nation.aspx>.

There is also an online version which can be accessed at the Compleat Lexical Tutor (<http://www.lex tutor.ca/range/>), and a freeware program—AntWordProfiler—developed by Laurence Anthony (http://www.antlab.sci.waseda.ac.jp/antwordprofiler_index.html).

The ease with which the analysis can be completed is dependent on the type of discourse and the number of running words in the text. A corpus is likely to take longer to analyze than a single text, and spoken discourse typically takes longer to analyze than written discourse because of the number of modifications to the text which may be needed. Computer programs can only read words according to their spellings. This means that if the spellings of words in the text do not conform to the spellings used to classify the items, then you need to decide what should be done about those words. This is likely to occur with connected speech, hyphenated words, proper names, and misspelled words. Typically researchers will go through the text and change these items to spellings which conform with those used in the software (see, for example, Nation, 2006; Webb & Rodgers, 2009a, 2009b). This is most easily done by piloting the text with the software and looking at the output to see which words are not identified by the program. In the RANGE program (Nation & Heatley, 2002) these words will be found in the output under *Types Not Found in Any List*.

Once the text has been run through the RANGE program, the output can be analyzed. The RANGE program provides two useful forms of data in the output. First, it provides the distribution of tokens, types, and word families in each word list. Typically, this indicates which words are high frequency, low frequency, and technical words, although this is dependent on the word lists used with RANGE. Table 1 is an example of the distribution of tokens, types, and word families from Webb and Rodgers's (2009a) analysis of 88 television programs, which used Nation's (2006) 14 BNC 1,000-word lists. These lists

Table 1 Tokens, types, and word families at each word level for all television programs (taken from Webb & Rodgers, 2009a)

Word list	Tokens		Types		Word families
	Raw	%	Raw	%	
1,000	225,011	85.11	3,169	22.79	996
2,000	11,675	4.42	2,269	16.32	963
3,000	5,095	1.93	1,457	10.48	820
4,000	3,439	1.30	1,019	7.33	694
5,000	1,872	0.71	739	5.31	539
6,000	1,307	0.49	519	3.73	422
7,000	857	0.32	386	2.78	333
8,000	560	0.21	292	2.10	250
9,000	525	0.20	267	1.92	231
10,000	401	0.15	181	1.30	168
11,000	339	0.13	207	1.49	187
12,000	230	0.09	122	0.88	109
13,000	179	0.07	116	0.83	106
14,000	103	0.04	73	0.52	70
Proper nouns	7,827	2.96	1,656	11.91	1,656
Marginal words	2,719	1.03	43	0.31	4
Not in the lists	2,245	0.85	1,392	10.01	??
Total	264,384		13,907		7,513

*The RANGE program is not able to calculate word families for words not in the lists.

Table 2 Cumulative coverage, with and without proper nouns and marginal words, for all television programs (taken from Webb & Rodgers, 2009a)

<i>Word list</i>	<i>Coverage without proper nouns</i>	<i>Coverage including proper nouns</i>
1,000	85.11	89.10
2,000	89.53	93.52
3,000	91.46	95.45*
4,000	92.76	96.75
5,000	93.47	97.46
6,000	93.96	97.95
7,000	94.28	98.27**
8,000	94.49	98.48
9,000	94.69	98.68
10,000	94.84	98.83
11,000	94.97	98.96
12,000	95.06*	99.05
13,000	95.13	99.12
14,000	95.17	99.16
Proper nouns	2.96	
Marginal words	1.03	

*Reaching 95% coverage.

**Reaching 98% coverage.

are accompanied by a marginal words list (containing words like *um, er, wow, gee*) and a list of proper names.

In the final row of Table 1 we can see that there were 264,384 running words, 13,907 word types, and 7,513 word families in the television programs. The studies which examined related and unrelated text looked at these figures to see how the vocabulary loads of different texts compare. In each of those studies the number of tokens was similar but the number of types and the number of families were smaller in the related texts indicating that the unrelated texts were lexically more demanding. The percentages of the tokens in the third column can be added together to determine the cumulative coverage. The cumulative coverage figures for the example above are shown in Table 2.

By adding the percentage of tokens found in the first 1,000 word list (85.11%) to the percentage of tokens found in the second 1,000 (4.42%) and third 1,000 (1.93%) word lists we can see that a vocabulary size of 3,000 word families would have 91.46% coverage of the running words in the television programs. The third column in Table 2 uses the same calculations but includes the percentage of proper names (2.96%) and marginal words (1.03%) in the totals. The cumulative coverage including proper names and marginal words at the 3,000 words level is thus $91.46 + 2.96 + 1.03 = 95.45\%$. This is the figure that leads Webb and Rodgers to suggest that a vocabulary size of 3,000 word families may be sufficient to reach 95% coverage of television programs. The argument for including proper names and marginal words in the totals is that learners with a vocabulary size of 3,000 word families are likely to be able to understand these items relatively quickly because their learning burden is lower than typical words.

The second part of the output which is useful for analysis is the data for each word. RANGE shows the number of times each word type and word family were encountered in the text and lists them according to the word lists used in the analysis. Examining the

Table 3 Number and percentage of encounters with word families in the fourth 1000-word list

	<i>Television corpus</i>	
	<i>Amount</i>	<i>Percentage</i>
1 encounter	224	32
2 encounters	132	19
3–4 encounters	135	19
5–7 encounters	103	15
8–9 encounters	25	4
10+ encounters	75	11
Total word families	694	100

number of times that words are encountered provides some indication of the potential for vocabulary learning, as well as which words might be considered to be technical words. Table 3 shows the number and percentage of word families which were encountered at differing frequencies in the fourth 1,000-word list for Webb and Rodgers's study of television programs.

Looking at the figures we can see that 11% of the word families were encountered 10 or more times, 30% of the word families were encountered five or more times, and 32% of the word families were encountered once. The figures provide some indication of the likelihood that words at this level may be learned through watching 35.1 hours of television programs. The running words which were encountered most often have the greatest potential to be learned. The words encountered only once or twice are less likely to be learned.

What Are the Limitations of Research on Vocabulary Load?

There are several limitations with computer programs used to analyze vocabulary load. First, words can only be classified according to their form. Thus homographs and polysemous words such as *bow* will be classified as belonging to the same word family whether the meanings found in the text refer to the front of a ship, a decorative knot, a weapon for shooting arrows, or bending at the waist or knees.

Second, because words are classified according to form, software cannot take account of proper names which have the same form as a word in one of the lists. For example, if proper names such as *Bush*, *Baker*, and *Field* occur in a text, they will all be classified as belonging to high-frequency word families because the same words cannot occur in different lists. In analyses of corpora this is likely to have a negligible influence on results, because when calculating coverage, proper name figures are usually included in the known words. However, studies of text with a small number of running words, and studies looking at the frequency of individual words, should take this into consideration.

Third, the RANGE program is unable to classify multiword items. This means that core idioms such as *by and large*, *so long*, and *beat it* will be classified according to their more frequent parts despite the difference in meanings between the single-word and multiword items. However, there are relatively few core idioms and most multiword items are figuratives which have a greater degree of overlap between form and meaning, and may pose fewer problems for learners (Grant & Bauer, 2004). This suggests that multiword items may not greatly influence results, but researchers should consider whether they pose any

threat to the validity of the findings. Updated software which can analyze single and multiword items according to their frequency of occurrence in the different word lists is one area where the technology used for analysis of word lists could be improved.

Fourth, it is also important to consider how the word lists used for analysis with the RANGE program were developed in order to determine whether the word lists may influence results. For example, Nation's (2006) fourteen 1,000-word lists were based on the frequency of occurrence of words in the BNC. The BNC is made up primarily of British written text which is more formal in nature. The word lists therefore reflect a bias toward more formal British English. This can be seen in the following list of headwords taken from the first and second 1,000-word lists: *bin, biscuit, bloke, bugger, chap, fortnight, lorry, motorway, muck, nick, nil, nought, parish, parliament, pence, petrol, pint, pound, pub, quid, rubbish, sack, and sod*. The frequency of items in a list is likely to vary based on the corpus from which they are derived.

Research on vocabulary load is gaining greater sophistication as there are developments in technology and the creation of word lists. This kind of research is valuable in its own right as it guides the setting of learning goals and the development of instructional material. This research is also a useful prerequisite to experimental studies on learning from text, in that it provides useful data on the nature of the vocabulary in the text. Such research is also useful for examining the potential and adequacy of the recommendations for learning as evidenced by the recent debate on learning through input (Cobb, 2007; McQuillan and Krashen, 2008; Cobb, 2008).

Computer-Mediated Communication and Second Language Development

SHANNON SAURO

Computer-mediated communication (CMC) is person-to-person communication that takes place via a range of computer-supported transmission technologies that enable both synchronous real-time and asynchronous interaction across different modalities. Thus, CMC encompasses such technologies as e-mail and text chat, blogs, vlogs (video blogs), bulletin boards and voice boards, and Web sites and wikis (a series of interconnected Web pages). Within language learning contexts, certain types of CMC are more prevalent, and accordingly research on language development that occurs during and through CMC reflects this tendency.

Historically, CMC for educational purposes can be traced back several decades to the development of computer-assisted instructional systems such as PLATO (Programmed Logic for Automatic Teaching Operations) and TICCIT (Time-Shared Interactive Computer-Controlled Information Television; Chapelle, 2001). The 1970s saw the development of programs that enabled users to leave personal letters for one another (the precursor to e-mail) or to page and initiate real-time communication with another user who was currently logged into the network (an early version of instant messaging or text chatting; Smith & Sherwood, 1976).

The late 1980s and early 1990s began to see the publication of articles in language research and language pedagogy journals that described the potential for CMC to support language learning. For instance, Ervin (1988) describes Compuserve's Foreign Language Education Forum, established in 1985, which supported e-mail and bulletin boards dedicated to foreign language learning, while Lunde (1990) advocates the use of e-mail as an inexpensive and quicker alternative to pen-pal exchanges and explores how e-mails can be produced in character-based languages like Japanese.

Moving beyond recommendations for classroom implementation, Kelm's (1992) description of the language produced by university learners of Portuguese during whole class interaction, and Beauvois's (1992) case study of a high school French learner's tutoring experience using InterChange, the synchronous CMC (SCMC) component of the Daedalus Instructional System package, represent a move toward integrating and evaluating text chat in language learning contexts. Further extending this line of research, Chun's (1994) longitudinal study of the language of beginning learners of German during class discussions using InterChange reveals the potential for CMC to support the development of interactive competence in a second language. During 14 chat discussions conducted over an academic year, Chun documented the numbers and functions of turns her students produced. Her analysis revealed the learners were able to produce a wide range of speech acts in the target language including asking and answering questions, greeting and leave-taking, and managing discourse by requesting clarification and providing feedback.

In the wake of these early studies exploring the use of text chat for language learning, the mid-1990s to early 2000s saw an increase in research on text chat that documented the amount and quality of language that learners produced in text chat compared to spoken interaction (e.g., Kern, 1995; Warschauer, 1996) as well as the amount of communication

repair or negotiation of meaning, generated during different types of communication tasks during text chat (Blake, 2000; Pellettieri, 2000; Smith, 2004). Results of these studies revealed that text chat discussion diverged from oral interaction with respect to the quantity and quality of language learners produced, yet resembled oral interaction with respect to the amount of negotiation fostered by different communication tasks.

Following this exploration of the quantity and quality of language produced and the types of tasks that supported strategies for repairing communication breakdown in text chat, researchers and instructors began to turn their attention to examining the enduring benefits of CMC for the development of skills and knowledge in a second language. Such studies focused either on the development of holistic language ability or on the acquisition of discrete language units such as vocabulary or specific grammatical structures.

Studies that examine more holistic second language development have looked in particular at the use of CMC to support spoken language or second language literacy. For instance, Payne and Whitney's (2002) semester-long examination of the influence of CMC on oral language development compared the oral production interview scores of learners of Spanish whose instruction included semi-weekly text chat discussions to those of learners who had participated in weekly spoken discussions in the classroom. While both groups improved, students in the text chat group showed significantly greater gains in oral proficiency measures than did the spoken discussion group. In a three-way comparison that investigated both SCMC and asynchronous CMC (ACMC), Abrams (2003) investigated the spoken language development of university learners of German who discussed readings in text chat (SCMC), on an electronic bulletin board (ACMC), or in face-to-face conversation (oral). Findings revealed that students in all three conditions performed similarly with respect to the complexity of the sentences they produced and the range of vocabulary used, while participants in the oral group and the SCMC group produced significantly more total words than did those in the ACMC group. Such studies provide some evidence that SCMC in the form of text chat can support oral language development.

While links have been made between the use of spoken language and SCMC, studies of second language literacy development have primarily looked to different types of ACMC and have focused on the emergence of specific literacy practices over time. For instance, Chen's (2006) two-and-a-half-year case study examined several hundred e-mails written by a graduate student from Taiwan to her peers and professors. Over time, the length and structure of her e-mails as well as the pragmatic strategies she used to make requests changed to reflect the e-mail norms of her university's culture. In another case study, Bloch (2007) examined the development of critical literacy and academic writing skills fostered by blogging in an academic writing course. Analysis of the blog entries and other writing samples produced by a generation 1.5 Somali learner of English revealed the development of argument structure and specific rhetorical strategies. As these case studies illustrate, research on second language literacy development using ACMC has typically illuminated language use and the process of language development, but has not attempted to make claims regarding the influence of the technology on writing skills.

In contrast to these studies examining the development of holistic language skills (e.g., speaking, writing) in the second language, another body of research has focused on the use of CMC to foster discrete vocabulary or grammatical knowledge. Such studies are typically of short duration, involve manipulation of the interaction, incorporate comparison groups, and focus in particular on text chat.

One such study which examined vocabulary development is Smith's (2004) study of adult English-language learners' ability to recognize and produce new vocabulary words after completing different types of communication tasks during text chat. In this five-week study, Smith used a pretest–posttest–delayed posttest design to evaluate his participants'

vocabulary learning by measuring their ability to both produce and recognize new vocabulary words encountered during the tasks. Results of this study revealed that negotiating the meaning of these unfamiliar words during text chat led to short-term sustained gains in vocabulary knowledge. Thus, Smith's findings provided evidence that negotiated interactions during CMC could facilitate second language vocabulary development.

With respect to studies of CMC and grammar development, the use of different error correction strategies during text chat has received particular attention. Sachs and Suh's (2007) comparison of two types of recasts, those that were underlined and those that were not, found that both types in a chat environment led to comparable improvement in backshifting of English verbs from simple to past perfect in reported speech among intermediate learners of English. In another study comparing the relative effectiveness of error correction types for grammar learning during text chat, intermediate and advanced Swedish learners of English were randomly assigned to one of three groups (recast, metalinguistic, and control) and received feedback on the use of the zero article with abstract nouns (Sauro, 2009). Participants receiving recasts or metalinguistic feedback demonstrated improved target form knowledge. Furthermore, the learners who received the metalinguistic feedback showed significant improvement over learners who received no feedback. The lack of significant learning by the control group in Sauro's study also suggests that, in the absence of corrective feedback or some other type of instruction, simply using text chat to communicate is not enough to support the development of certain grammatical features in the short term.

However, the findings of these two studies, which involved intermediate and advanced language learners, stand in contrast with those of an earlier study (Loewen & Erlam, 2006), in which beginning-level learners of English who received feedback on errors with the past tense *-ed* did not outperform participants who received no feedback. Taken together, these studies provide evidence for the short-term benefits of certain types of error correction during text chat for grammar development for learners with sufficient proficiency.

Understanding for which types of learners CMC may hold the greatest advantage for second language development is another promising direction for future research. Representing one such example of this line of work is Payne and Ross's (2005) investigation of whether learners' working memory capacity might be related to the degree of oral proficiency development following a semester-long Spanish-language course that incorporated two chat discussions per week.

However, the individual, contextual, or linguistic factors that may influence the effectiveness of CMC as a tool for second language development still remain relatively unexplored. As details from the studies described above suggest, most of our understanding of CMC and second language development stems from research with adult learners using written CMC, especially text chat and to a lesser degree e-mail, to communicate in and learn languages that use alphabetic writing systems. Pedagogically informative future research on CMC for language development will need to incorporate different learner populations (e.g., younger learners, learners not in university classrooms), a broader range of CMC modalities and formats (e.g., voice boards, wikis, voice chat), and target languages with different orthographic systems and keyboard input methods (e.g., simplified Chinese, traditional Chinese, Arabic) to reflect the broad range of pedagogical contexts in which CMC can be used to support language learning.

Computer Scoring of Spoken Responses

JARED C. BERNSTEIN

Scoring oral test responses by computer is the estimation of spoken language ability or its component skills by the operation of a computer on one or more spoken responses that are presented within an oral language test. This estimation process will be referred to here as *computer scoring of spoken responses* (CSSR). As shown in Figure 1, automatic scoring is one component in a system for computer-based testing (CBT) that may present, record, and distribute spoken response material. CSSR refers to the automatic analysis and scoring of the responses that have typically been collected through such a CBT system.

Figure 1 also shows the basic processing in CSSR within a CBT system. A speech signal is picked up and recorded, then processed by a speech recognition system, the output of which is sent to scoring modules, which return component scores that are combined according to a score-integration logic, then displayed in a score report. As of 2011, automatic oral response scoring may focus on the content of the speech, which may include its turn structure, pragmatic force, linguistic form, and lexical content. Scoring may also focus on qualities of the speech itself, such as its fluency and pronunciation, or may combine content and quality aspects into a more general estimate of speaking ability.

Current CSSR systems estimate speaking ability by combining measures of linguistic and lexical structures with measures of fluency and pronunciation, returning scores with high consistency and acceptable accuracy, although the construct validity of some tasks and scoring methods has been questioned.

Why Use CSSR?

Human scoring of speaking has been shown to be valid for some purposes, but reliable human scoring is difficult to establish and maintain, even over a coarse six-level scale and even when well-trained raters use carefully constructed scoring rubrics. Score consistency is especially difficult across different language environments, across items, and over time, in part because there is a tendency for human raters in any judgment task to drift or shift to fit the range and distribution of exemplars in a sample (Parducci, 1995). Counteracting

Figure 1 Schematic view of CSSR within a CBT system

natural human tendencies that cause scale-shift within and across human judges requires effective training and equating procedures that can add cost to human-scored speaking tests.

Automatic scoring of spoken performances addresses some of the problems of human scoring. For example, permanent equilibration is possible for a standard distribution of skill levels across samples of speakers of different first languages. Automatic scoring can be calibrated once and reproduced on as many machines as needed to score millions of exams, and then score new material the same way at any later time. These advantages may also carry with them lower costs to the test taker and much shorter scoring delays.

History of CSSR

CSSR applies techniques from several more basic (and overlapping) fields including automatic speech recognition (ASR), spoken language processing, computational linguistics, and statistical pattern recognition (Jurafsky & Martin, 2009). ASR forms the core of a CSSR system. The earliest ASR systems were implemented in analog hardware in the 1950s; the first digital implementations of ASR appeared in the late 1960s and were first commercially viable in the 1990s in telephony. Eskenazi (2009) reviews the development of educational applications of ASR as it started appearing in the 1990s. Aist (1999) and Ehsani and Knodt (1998) present even more time depth, reviewing visual feedback systems from the 1970s and 1980s that were used for language learning. For example, Nickerson and Stevens (1973) describe a sophisticated real-time feedback system used in deaf education that ran on hybrid analog/digital processors and displays.

Methods

Although CSSR is often applied in assessment tasks that require both listening and speaking, we limit the scope here to estimating speaking ability only, disregarding the mode of item presentation. Accurate CSSR depends on many factors, but important elements include the size of the unit to score, the predictability of the spoken material, and the number of independent measurements combined in estimating the score. Some applications of CSSR, such as error detection in an interactive pronunciation tutoring system, are inherently more difficult than others. Recognition of the correct answer read aloud from a multiple-choice list, for example, is an easy task for ASR. As is common in engineering, the nature of the application guides the selection of method.

Pronunciation tutors are considered important applications for foreign language instruction because spoken interaction with expert pronunciation feedback may not be easily available to learners. A learner of English or an instructional designer may expect that the assessment component of the machine should be able to “hear” a sentence, then accurately detect the mispronounced segments (phones) and provide tutor-style guidance to encourage correct production. This would rely on quality scoring, as shown in Figure 1, applied to a sequence of recognized segments, each of which is a short event with 5–25 acoustic observations. In the error detection scenario, a speech recognizer produces its best estimate of the spoken words and submits a time-aligned transcription of the phones in the spoken response to the quality scoring module. So, for example, in a 1-second utterance of “Sweep the kitchen,” the first subprocess inside the ASR module analyzes the speech signal into a sequence of 100 spectra, and assigns the first 9 spectra to [s], the next 7 spectra to [w], the next 14 spectra to [i], and so forth. Thus, each phone in each word has an associated sequence of spectra, from which the pronunciation tutor is expected to make a judgment of whether or not these spectra should count as a good exemplar of the recognized phone.

The most common and basic approach to scoring pronunciation quality is to combine a spectral likelihood ratio (sometimes used as a confidence measure) with the duration of the phone (which is just the number of spectra assigned to that phone from the sequence of spectra in an utterance). The likelihood ratio highlights the relative compatibility of the observed spectra with the expected acoustic properties of the recognized phone that has been aligned with these spectra. The calculated likelihood ratio, given a series of observed spectra and a recognized phone, is of the form:

$$\text{Pronunciation score} = \frac{\text{Probability of these spectra given the recognized phone}}{\text{Average probability of these spectra given any other phone}}$$

This ratio effectively normalizes the score for channel distortion and voice quality, as both the upper and lower term are affected by these factors. Similar methods are described by Franco et al. (2010) as applied to Spanish spoken by English speakers; Strik, Truong, de Wet, & Cucchiari (2009) describe and compare related methods for error detection in a two-way distinction between [k] and [x] in non-native Dutch.

Again, an important consideration is the total duration of the sample to be scored; and if one is picking out problem segments in a single utterance, the nature of the segment matters too. Franco et al. (2010) found that for most segment types in Spanish, human-human agreement on the “nativeness” of a single production of a phone yields kappa values below 0.3. That is, in many cases native listeners do not agree about the acceptability of particular instances of phones, although they may well have high confidence in their judgments.

Figure 2 shows how machine scores improve with the increasing duration of the stretch of spoken material that is scored. The data shown is for a sample of 50 adult learners of English with a variety of first languages. Three phone-classes are shown: the short solid line shows all and only /r/ segments; the dashed line shows all /r/, /ə/, and /w/ segments, and the long solid line show all segments taken together. For each class, for a set of 50

Figure 2 For three classes of phones, correlation between listeners’ overall human-rated pronunciation scores and corresponding CSSR score as a function of the cumulative signal duration that CSSR operates on $n = 50$ test takers

test takers speaking in response to an English speaking test, the line shows the value of the correlation between a machine pronunciation score and a reliable composite human score of overall pronunciation for the speakers based on many recordings of each speaker rated by several judges.

Taking 0.1 seconds as a typical phonetic segment length, it can be seen from Figure 2 that a machine can produce speaker pronunciation estimates from two or three tokens of /r/ that correlate with a speaker's overall human-rated pronunciation score with a value of about 0.6, while if all segments are considered, it would likely take about 24 phones to produce a similar correlation with human ratings. In summary, for single pronounced tokens of a phone in context, accurate automatic detection and diagnosis of errors is a challenging technical task that attempts to match a human judgment that Franco et al. (2010) have shown to exhibit generally low agreement between pairs of human raters.

Summative assessment of speaking ability is a more general task that typically includes pronunciation scoring as a component, but can return more accurate and reliable scores because it may reasonably be based on one or more minutes of speech and use several independent sources of information from a set of spoken responses.

Referring back to Figure 1, a summative assessment can be extracted from a set of spoken responses by combining estimates from several different kinds of evidence that can be combined into an overall estimate. Because cultural expectations permit an assessment to last more than an hour and to elicit many short samples or several long samples of speech, or both, capturing 5 or 10 minutes of spoken material for computer scoring is culturally acceptable. The "All segments" line in Figure 2 suggests that even with only 2 or 3 minutes of speech, an overall pronunciation score can be accurately estimated.

However, there may be four or more scores coming from the content and quality analyzers, as schematized in Figure 1, which can be combined to produce a summative score that correlates closely with human summative judgments. For example, summing just two automatically extracted measures of linguistic content (syntactic structure and vocabulary) and two automatic measures of production quality (fluency and pronunciation) from 3–4 minutes of speech produces very high correlations ($r = .97$) with sums of corresponding human ratings of the same spoken materials (Bernstein & Cheng, 2007). In this implementation, the individual automatic sub-scores correlate with the human scores with values of {0.93, 0.94, 0.89, 0.89}. In part, because the cross-correlation of the automatic sub-scores averages about 0.72, the machine–human correlation of the summed scores reaches 0.97 for a human summed score with a reliability of 0.98.

Note that in 3 or 4 minutes of spoken material responding to 20–60 spoken prompts, a test taker may produce 2,000 or more phones, 40 or 100 phrases or clauses that perhaps include 40 or as many as 500 words. Given a relatively accurate scoring of these semi-independent content and quality aspects of the person's speech, an accurate overall score can be reported.

Explanation

Although CSSR techniques will produce only a rough estimate of a person's oral proficiency from that person's production of one unit of spoken language, when many of these noisy estimates are summed, the result asymptotes toward the human summative rating. CSSR works best on constrained tasks for two reasons. First, the component content and quality estimates are constrained by the accuracy of the underlying speech recognition technology, and predictability of the spoken material is a main determinant of ASR accuracy. Second, when tasks elicit relatively predictable spoken responses, test developers can build much tighter performance models from samples of speakers of various levels. That is, within a

constrained context, the variance of many acoustic, lexical, and rhythmic units is reduced, especially in high-proficiency speech, and the variance of these units then can be used as a yardstick in scoring other spoken responses.

In the work presented by Bernstein and Cheng (2007), the performances scored are produced in real time—without any preparation time or note taking. Evidence from Hulstijn (2007) suggests that apparent automaticity is a key element in judgments of general speaking ability. If so, the unprepared nature of a task may bring out aspects of automaticity in performance that are particularly salient to listeners and interlocutors in real conversation.

Challenges

As of 2011, CSSR techniques yield less reliable scores for spoken-answer tasks that elicit widely variable or unpredictable responses. This is partly because speech recognition relies strongly on “top-down” processing, which is typically implemented in ASR and CSSR systems as a statistical language model (LM). LMs are conceptually similar to expectation grammars in the applied linguistics literature (Oller, 1971); however, LMs usually model word–word dependencies, thus mixing lexical and syntactic expectation. LMs, therefore, are quite topic sensitive, as human listening is under unfavorable noise conditions.

An example to clarify: A language model based on n-grams uses the previous words to predict the next word, on the basis of probability estimates derived from transcribed speech in response to the same assessment prompt. Thus, given *raise income tax* an LM might strongly predict *rates* to be the next word, because *raise income tax rates* is a commonly occurring 4-gram (4-word sequence) in response to a given prompt. The same kind of LM prediction could be made for a 3-gram like *income tax rates*, or a word pair like *tax rates*, and the unigram probability for the word *rates* (without any information about the preceding words) is helpful recognizing speech.

Although ASR takes advantage of some of the top-down expectations that human listeners use, many features of ASR behavior are not similar to human performance. ASR systems do not produce errors in patterns similar to human listeners’ patterns of errors, and systems need to be designed with this difference in mind. One notable difference is that human listeners are quite good at isolating a single unknown word in a sequence, while ASR technology does not return reliable “confidence” scores for single words. For example, a reasonably common human exchange might be:

Speaker 1: *The [unintelligible] one didn’t show up.*

Speaker 2: *The which one didn’t show up?*

The listener (speaker 2) was sure of all the words but one and then asked for that one. Like pronunciation scoring, ASR lexical decision is not very reliable on a single word; the processes gain accuracy over sequences of several words. In the ASR literature, this is called the “Out-of-Vocabulary” (OOV) problem, and no general solution is yet available that enables automatic dialogue turns like speaker 2’s question.

Future Directions

There may be broadly two directions of future enhancement for CSSR: One is analysis for sharper diagnostic reporting, and the other is reintegration of speaking skills with cognitive and social skills to reconstitute the traditional communicative spoken language construct from more elemental constructs. First, and most simply, many of the tasks that elicit spoken responses use spoken prompts, so one can presume that response performances

are partly dependent on listening as well as speaking. It would be good to test speaking with tasks that elicit the kind of spontaneous speech found in natural dialogue without conflating the speaking scores with listening skills. Second, there are many perceptible qualities of the speech itself that cannot be reliably scored from unconstrained samples; examples are indexical properties like friendliness, or affective properties like apparent mood. Lastly, it would be useful if articulation and prosody in speech could be analyzed such that the most effective route toward phonological improvement was known for a given speaker.

The reintegration of CSSR with those cognitive and social aspects of live communication will depend on ongoing development of technologies that extract features of declarative and social meaning, and that are still nascent in applied linguistics and in spoken language engineering.

Conceptualizing and Researching “New Literacies”

COLIN LANKSHEAR, MICHELE KNOBEL, AND CAITLIN CURRAN

References to “new literacies” have become increasingly common as use of digital technologies has grown within everyday routines, reflecting a growing sense that “literacy” can no longer be presumed to refer simply to interactions with conventional texts.

New Literacies as a General Concept

“New literacies” mostly functions as an umbrella term for myriad everyday interactions with *digital* texts. The term “text” has itself been amplified to extend far beyond alphabetic–typographic texts alone. “Text” now covers all manner of multimedia artifacts that people can be said to read and write, interpret, and make meaning from in their daily lives. As a general classification, “new literacies” typically refers to interactions with digitized textual material and other digital media. It is a general referent for “information literacy,” “multimodal literacy,” “digital literacy,” “(multi)media literacy,” “Internet literacy,” and so on (Coiro, Knobel, Lankshear, & Leu, 2008a). Understanding and using new media and technologies competently is another conception of “new literacies.” In this sense, being “savvy” with digital tools and techniques is seen as a new literacy (e.g., computer literacy).

Numerous scholars also identify examples of new literacies that do not necessarily entail use of digital technologies and digitally coded meanings. These are literacies that can be regarded as *chronologically* rather than *ontologically* “new” (Lankshear & Knobel, 2003, p. 17) with one or more of the following characteristics: they are relatively recent—or recently popular—forms of literacy practice; they have only recently been conceived of as literacies; only recently have they been considered as literacies with which formal education should engage. Diverse “new” literacies of this type include (critical) media literacy, print-based zines and fan fiction, strategy card games, analogue media remixing, graphic novels, and certain forms of iconic and logo-based communications.

Specific Conceptions of New Literacies in Research and Theory

In contrast with such umbrella uses, researchers and scholars have begun conceptualizing new literacies in ways intended to help understand and explain a range of developments in human interaction and communication under contemporary media conditions. Several approaches can be distinguished—albeit with significant overlaps among them—within academic literature dating from the late 1990s.

New Literacies in the Context of a Changing Communicative Order

Brian Street (1998) conceptualizes new literacies by reference to a changing *communicative order* in which a range of nonlinguistic semiotic systems “cut across reading, writing and speech” (p. 9). Increased use of icons, images, and visual displays, as well as combinations

2 CONCEPTUALIZING AND RESEARCHING “NEW LITERACIES”

of text and images within instruction manuals, safety procedures, warnings, and the like are typical examples of changing communication patterns. There is no *necessary* association with digital technology use here, although a strong and growing contingent association exists. Examples include making meaning from postcards, logos, and information charts comprising graphics and alphabetic text. The emphasis is on multiple media, formats, and sign systems at work in ways of communicating meaning. Communicative competence requires mastering new literacies: acquiring grammars of visual and multimodal design for reading and writing hybrid text types comprising linguistic and nonlinguistic signs, managing tools for consuming and producing multimodal texts, and mastering changing discourses within work environments and key social institutions. This conception of new literacies emphasizes heteroglossia over linguistic essentialism and “purity,” and communicative efficacy over deference to long-established systems of linguistic rules and conventions. In particular, it challenges “school-centric” literacy education that privileges forms of discourse and approaches to vocabulary, grammar, and syntax that are increasingly out of touch with contemporary communication needs outside of formal educational settings.

New Literacies and Democratic Citizenship

Douglas Kellner (2000) advocates the need for educators to engage with and promote a variety of new types of literacies to make education relevant to the demands of a global postindustrial and networked society that is multicultural and democratic—with a particular emphasis on empowering individuals and groups traditionally excluded from full economic, political, social, and cultural life. This requires developing “new forms of media literacy, computer literacy, and multimedia literacies,” or new forms of “multiple literacies” (p. 249). Kellner advocates a *critical* media literacy that “teaches students to learn from media, to resist media manipulation, and to use media materials in constructive ways,” and develop “skills that will cultivate citizens and . . . make them more motivated and competent participants in social life” (p. 251). He argues for an expanded concept of computer and information literacy that “involves not just technical knowledge and skills, but refined reading, writing, research, and communicating ability that involves heightened capacities for critically accessing, analyzing, interpreting, processing, and storing both print-based and multimedia material” (p. 254).

New Literacies of the Internet

During the past decade an ongoing research program involving Donald Leu and colleagues has emphasized the central importance of the Internet to conceptualizing new literacies (Leu, O’Byrne, Zawilinski, McVerry, & Everett-Cacopardo, 2009). The new literacies of the Internet result from the fact that the Internet, as a powerful technology for literacy, “permits the immediate dissemination of even newer technologies of literacy to every person on the Internet by connecting to a single link on a screen” (Coiro et al., 2008a, p. 3). Under these conditions literacy becomes *deictic*: literacy is continually redefined amidst constant technological change and has meaning only on a case-by-case, context-by-context basis. Literacy has come to mean “a rapid and continuous process of change in the ways in which we read, write, view, listen, compose and communicate information” (Coiro et al., 2008a, p. 5). Given that literacies will continue to be multiple and rapidly disseminated, the concept of literacy acquisition becomes radically different from that of the print era. It will henceforth require “a larger mindset” and ability and disposition to adapt to regular changes in the means and protocols for communication and information exchange. Within this conception, Leu and colleagues have focused particularly, though not exclusively, on *epistemic* aspects of literacy: on comprehending and evaluating information accessed online.

New Media Literacies

Jenkins and colleagues define new media literacies as “a set of cultural competencies and social skills that young people need in the new media landscape” (Jenkins, Clinton, Purushotma, Robison, & Weigel, 2006, p. 4). “New media” comprise “new sites of audience expression” made possible by digital technologies (Jenkins et al., 2006). Buckingham (2008) and Marsh (2005) similarly speak of digital media literacies that mobilize forms of textual and visual representation, language and communication codes and conventions, production processes and practices, and audience understandings. From a new media literacies perspective, using new media blurs “the boundaries between mass communication and interpersonal communication, and between producers and consumers” (Buckingham, 2003, p. 310). “Participatory culture” is central to Jenkins’s conception of new media literacies. This is “a culture with relatively low barriers to artistic expression and civic engagement, strong support for creating and sharing one’s creations, and some type of informal mentorship whereby what is known by the most experienced is passed along to novices” (Jenkins et al., 2006, p. 3). Members of participatory cultures feel valued and socially connected to one another. Participating in fan fiction cultures, for example, includes writing and posting stories online for review, providing writing hints and tips for each other, contributing to fan blogs or discussion boards, creating music and video clips, and so on, drawing on and contributing to a shared pool of fan-produced media products and resources. Buckingham (2003) argues that such participation requires the development of new forms of critical analysis and ideology critique to effectively harness the productive possibilities of new media literacies.

New Literacies—Integrating Production and Consumption

Numerous writers argue that using new technologies to decode and produce meanings using symbols involves an intense integrated relationship between the consumption (reading) and production (writing) dimensions of signifying and representational practices (e.g., Jenkins, 2006; Gee, 2007; Bruns, 2008; Ito et al., 2010). Within print literacy the orientations and roles of producer and consumer of texts often seem quite distinct. Concepts like critical literacy and critical reading emerged in part to focus on the value of readers reflecting on the design of texts from their authors’ perspectives. In many digitally mediated literacy practices, however, the acts and roles of consuming and producing have become inseparable. To play video games successfully, “gamers must think like games designers; they must at least think about how elements of game design work to help or hinder their goals as players” (Gee, 2007, p. 135). Furthermore, tinkering with game engines (software) means that players can modify games in different ways and even design entirely new games (Gee, 2007). Emphasis on operating as *both* consumers and producers is marked across diverse popular cultural pursuits involving new technologies. These include various fan practices involving participation in affinity spaces (Gee, 2004; Jenkins, 2006), such as digital music and video remixing, certain kinds of animation (e.g., machinima), and fan fiction, as well as practices such as blogging, photosharing, participating in discussion forums, and elements of online social networking.

Digital Technologies and Collaborative Ethos Within Contemporary Literacy Practices

A social practice approach to literacies focuses on shared ways of creating and exchanging meanings within social contexts in which participants use tools and knowledge to meet goals with respect to who they are and what they are trying to achieve within those contexts (Scribner & Cole, 1981). From this perspective it has been argued that new literacy

practices are characterized by use of digital tools and techniques in conjunction with a distinctive ethos or sensibility (Lankshear & Knobel, 2006). The *technical* dimension of new literacies includes, for example, such things as knowing which icons to click on screen, understanding file management systems, and knowing how to convert files from one format to another. The *ethos* dimension of new literacies refers to the intensely “participatory,” “collaborative,” and “distributed” nature of many current literacy practices. New literacies draw on collaborative dispositions and ways of participating, supported by distributed digital networks and other Web 2.0 technologies. They emphasize participants accessing and “developing” the distributed knowledge of communities of interests, where experts and novices work together as peers to support and advance their individual and collective ends (Benkler, 2006; Lankshear & Knobel, 2006). New literacy practices enact values and ways of generating, sharing, and remixing resources and ideas to build and enrich cultural stock. Typical examples include participating in fan fiction and anime music video remix affinity spaces, contributing to wikis, blogging, and using collaborative online writing spaces to complete shared projects.

Researching New Literacies

Orientation to Theoretical Development

Coiro et al. (2008a, p. 12) distinguish between (a) approaches to researching new literacies that import theoretical perspectives developed within contexts of traditional literacy research and (b) embryonic research approaches that make Internet and other digital technologies and the social practices these enable central to research and build out from there. They argue that new literacies are sufficiently distinctive as to require their own theoretical integrity grounded in “the social practices of [new literacies] . . . and the context and conditions under which these social practices occur, develop and evolve.”

Theoretical Range

To date, individual studies of new literacies have typically drawn on single traditions of inquiry, such as cognitive theory, sociolinguistics, psycholinguistics, sociocultural or sociotechnical theory, and media or communications theory (or both), although numerous mixed-method studies (e.g., Bruce & Bishop, 2008; Burn, 2008) range over multiple perspectives. Notwithstanding the dominance of single traditions, new literacies research collectively reflects a rich diversity of specific theoretical preferences and more general theoretical perspectives. For example, approaches to investigating the politics of new literacies in relation to issues of access, equity, citizenship, and the like range across variants of critical theory, demographics, economics, network theory, and mathematical studies of power law distributions. Studies of video games as new literacies draw on cognitive science, discourse theory, social semiotics, sociolinguistics, economics, law, cognitive and social psychology, design studies, educational technology, social constructionism, among others (e.g., Steinkuehler, 2008). Research into the distinctive character of online reading comprehension (Leu et al., 2005) draws on theory from such fields as cognitive psychology, cognitive science, psycholinguistics, constructivism, and metacognition. Studies at the interface of language acquisition and maintenance and participation in online social practices and affinities (e.g., Black, 2008; Lam, 2009) draw on language acquisition theory, discourse theory, sociolinguistics, social practice theory, the sociology of transnational migration, and social theories of identity, among others. Other new literacies research interests draw on such diverse theoretical options as sociotechnical theory, social construction of space and time, postcolonial theory, feminist theory, hermeneutics, informatics, communications

theories, theories of culture, network theories, and so on (for a wide sampling, see Coiro, Knobel, Lankshear, & Leu, 2008b).

Methodological Approaches

New literacies research spans a wide range of design types, including experimental and quasi-experimental and large-scale quantitative designs (including surveys), discourse studies, ethnographies, case studies, text and multimodal analysis designs, interview-based designs, and various mixed-method and hybrid designs. Questionnaires, evaluative tests, interviews, participant and nonparticipant observation, interviewing, artifact collection, screen capture, in situ conversations with a purpose, think alouds, walk-throughs and talk-throughs, written transcript collection, textual documentation of technical resources, network mapping, audio and video recording of interactions, use of eliciting devices, and the like are among the staple means of data collection in new literacies research (Coiro et al., 2008b). Data analysis options are likewise diverse. Quantitative designs employ familiar statistical analyses, such as analysis of variance and covariance, cluster analysis, cross tabulations, and descriptive statistics. Popular options within qualitative studies include various forms of discourse and linguistic analyses, inductive and interpretive coding, narrative analysis, theme and category analysis, rhizomatic analysis, network analysis, spatial analysis, and social semiotic analysis, among others. Mixed-method and hybrid design studies employ various combinations of analyses within and across the kinds of quantitative and qualitative options mentioned.

New Literacies Research

Research concerned explicitly with advancing knowledge and theory of new literacies has burgeoned since the 1990s. Among the diverse emphases apparent within the overall field, the following are especially visible.

Studies of Fan Practices

This corpus investigates forms of literacy engaged in by people who are active fans of some phenomenon (notably, writing fan fiction, creating fan videos, participating in fan-based discussion boards). Affinities, participation, and collaboration are key organizing and explanatory concepts (Jenkins, 2006). Ethnographic designs employing fieldnotes, artifacts and interview data, analyzed by inductive coding and various linguistic and discourse analysis techniques are popular (Black, 2008; Ito et al., 2010; Lam, 2009).

New Literacies as Digital Production Practices

Studies here focus on creation of digital products and artifacts that are not necessarily linked to fandoms—such as studies of digital storytelling, digital music composing, digital photography, and curating online photographs studies, creating flash animations, stop motion animation, website construction, and machinima making (e.g., Hull, 2004; McClay, Mackey, Carbonaro, Szafron, & Schaeffer, 2007).

Online Reading Comprehension

A growing body of studies investigates school-age children’s online information-processing and reading-comprehension strategies, with particular emphasis on how reading online differs from traditional print-based reading (Leu, O’Byrne, Zawilinski, McVerry, & Everett-Cacopardo, 2009). This body of work also addresses the means by which and extent to which students actively evaluate online information.

Social Networking and Online Communication

Considerable research focuses on engagement with online networks and communication media. Focus areas include participation in social networking sites such as Facebook and Myspace and online discussion forums, as well as communication practices like instant messaging, blogging, twittering, and the like (e.g., Lewis & Fabos, 2005; Davies & Merchant, 2008; Lam, 2009). Studies often address the (dis)continuity between these new literacies and the forms of literacy encountered in formal education settings.

Video Gaming

Video games and gaming practices are a well-established focus for new literacies research (cf., Squire, 2008; Steinkeuhler, 2008), proceeding from the standpoint that game design involves a multimodal code comprising images, actions, words, sounds, and movements that players interpret according to gaming conventions and meanings (Gee, 2007, p. 135). Studies often employ onscreen game-play recordings, interviews, fieldnotes, discussion board transcripts, e-mails, community documents such as player-generated walkthroughs, and manuals. Forms of linguistic and discourse analysis are widely used.

New Literacies and Classrooms

Many researchers are interested in how to incorporate new literacies effectively into classrooms and, particularly, with how to implement and evaluate new literacies projects in school and after-school settings (Brass, 2008). Increasing attention also is being paid to developing and evaluating options for assessing new literacies within formal education (Burke & Hammett, 2009).

Concordancing

CHRISTOPHER TRIBBLE

What Is a Concordance?

For most language teachers and lexicographers, a concordance will be a computer-generated listing of all of the instances of a word in a collection of texts. Such a concordance for the word *rabbit* in Lewis Carroll's *Alice in Wonderland* would look like Figure 1.

More formally, a concordance can be defined as "a collection of the occurrences of a word-form, each in its own textual environment. In its simplest form it is an index. Each word-form is indexed and a reference is given to the place of occurrence in a text" (Sinclair, 1991, p. 32). This definition is important because it reminds us that, originally, a concordance was a manually prepared list of the word forms found in a text or set of texts along with references to their precise locations (by book, verse, line, etc.). *Word form* is stressed here because at a basic level it would require separate searches to find the singular and plural form of, for example, *cat* and *cats* in a corpus.

The first recorded concordance in the Western tradition was based on the work of Cardinal Hugo of St Caro, who, "with the help of hundreds of Dominican monks at St James convent in Paris, compiled a word index of the Vulgate in the year 1230" (Bromiley, 1997, p. 757). Given the huge human effort involved in such a project, it is not surprising that in the pre-computer age, these were only developed for a few culturally valued texts (e.g., Cruden's 1738 *A Complete Concordance to the Holy Scriptures*, Strong's 1890 *Exhaustive Concordance of the Bible*, or Becket's 1787 *A Concordance to Shakespeare*). These books provided scholars with two kinds of resource. The first was a comprehensive account of where words were used in a closed set of texts (in Strong, 1890, the 8,674 Hebrew root words in the Old Testament and the 5,624 Greek root words in the New Testament). The second, (e.g., Becket 1787) was designed as a source of insight and illumination for a wider readership, with an example of the word being given along with its linguistic context and location in the Shakespeare canon (play, act, scene), as in the example for *WORD* in Figure 2.

In computer-assisted linguistic analysis, concordances continue to be, at heart, indexes of instances, but they can be generated for a range of new purposes and across an ever-expanding range of texts and text types. A printed concordance of a Greek root word in Strong (1890) would have assisted scholars concerned with biblical exegesis by giving a comprehensive account of how often and where this word was used across the King James Authorized Version of the New Testament. Indeed, this tradition continued until the 1990s

cking the daisies, when suddenly a White Rabbit with pink eyes ran close by her. so VERY much out of the way to hear the Rabbit say to itself, 'Oh dear! Oh dear all seemed quite natural); but when the Rabbit actually TOOK A WATCH OUT OF ITS er mind that she had never before seen a rabbit with either a waistcoat-pocket, was another long passage, and the White Rabbit was still in sight, hurrying dowa d it when she turned the corner, but the Rabbit was no longer to be seen: she fo to see what was coming. It was the White Rabbit returning, splendidly dressed, wady to ask help of any one; so, when the Rabbit came near her, she began, in a l timid voice, 'If you please, sir--' The Rabbit started violently, dropped the w

WORD	
What laid he? How looked he? Wherein went he? What makes he here? Did he ask for me? Where remains he? How parted he with thee? And when shalt thou see him again? Answer me in one word. <i>As you like it</i> , A. 3, S. 2.	
— Hear me, Hubert! drive these men away, And I will fit as quiet as a lamb; I will not air, nor wince, nor speak a word, Nor look upon the iron angerly : Thrust but these men away, and I'll forgive you. <i>King John</i> , A. 4, S.	
— These haughty words of hers Have batter'd me like roaring cannon-shot, And made me almost yield upon my knees. <i>Henry VI. P. 1</i> , A. 3, S.	
Gregory, o' my word, we'll not carry coals. <i>Romeo and Juliet</i> , A. 1, S	

Figure 2 Concordance for *word* in Becket’s *A Concordance to Shakespeare* (1787), p. 458

with printed concordances of Henry James (e.g., Bender, 1987), Joseph Conrad (e.g., Bender, 1979), and T. S. Eliot (Dawson, Holland, & McKitterick, 1995).

Useful as these concordances have been to scholars, a computer can now be used to create an equivalent to the Strong concordance in the blink of an eye, and it can also support a much wider range of analytic purposes.

Computer-Generated Concordances:
Approaches, Tools, and Resources

Earlier Traditions

Before the days of digitized texts and modern computers, concordances were made by dedicated individuals or teams, working often over long periods of time. Team members would read the text, identify words that mattered to the analysis, and painstakingly build up tables which recorded where each instance of that word was found. A paper-based concordance for *rabbit* in *Alice in Wonderland* could take two main forms.

Assuming a text in which article, page, and line numbering are known, a concordance in the Strong (1890) tradition might give us an entry for *rabbit* such as the one in Figure 3.

Each time the word *rabbit* appeared in a page, the tally would be increased and a cumulative log would be kept of the article, page, and line reference so that a cumulative total and list of locations could be compiled at the end of the research process.

count	word	article	page	line
1	rabbit	1	1	9
2				12
3				15
4				18
5				21

Figure 3 Basic index concordance for *rabbit*

A concordance in the Becket (1787) tradition might look more like this:

...when suddenly a White Rabbit with pink eyes ran close by her
(Article 1, p.1, 1.9)

Alice started to her feet, for it flashed across her mind that she had
never before seen a rabbit with either a waistcoat-pocket, or a watch
to take out of it ... (Article 1, p.1, 1.18)

the editor having decided that these two uses of *rabbit* were more interesting than other instances in the text.

Simple Concordances

In contemporary computer-assisted analyses of texts, we expect to be able to access all the information we would find in a paper concordance (i.e., frequency of occurrences and exact location in the text) along with a great deal more. Using a modern concordancer such as WordSmith Tools version 5 (Scott, 2008), which has been used to generate all the original examples here, it is possible to look at a word form in a number of ways—each of which has its value for the researcher.

As a way of demonstrating the principle which underlies a concordance, Sinclair (1991, p. 33) gives an example of a concordance of a complete short text, *The cat sat on the mat* (see Figure 4). Here, each word is treated as a *node* word form (i.e., the string of characters which the computer has been instructed to search for in the corpus). These notes have then been sorted in alphabetic order (rather than being presented in text sequence) and a one-word-form context at either side has been provided.

the	cat	sat
the	mat	
sat	on	the
cat	sat	on
	the	cat
on	the	mat

Figure 4 One-word-form context concordance (adapted from Sinclair, 1991, p. 33)

Although such full text concordances continue to be a possibility, it would be unusual to use this approach for larger texts or text collections. A more common format is one in which a single node or search term (this can be a word form or phrase) is looked for in all its contexts across a text. Given in Figure 5 is the same Key Word in Context (KWIC) concordance for the word form *rabbit* which was used in Figure 1. In the current display, the first 10 occurrences of the word form are presented in text sequence at the center of a context of 70 characters (spaces and punctuation are counted as characters).

Figure 5 KWIC concordance for *rabbit* in *Alice in Wonderland*

4 CONCORDANCING

It should be remembered that the KWIC format is not the only way of displaying concordance data, and that it is not always the best. The concordance extract in Figure 6 gives an alternative view of the same data, but this time complete sentences are shown and the node word is underlined.

```
N                      Concordance
1
1 'So she was considering in her own mind (as well as she could, for the hot day made
her feel very sleepy and stupid), whether the pleasure of making a daisy-chain
would be worth the trouble of getting up and picking the daisies, when suddenly a
White Rabbit with pink eyes ran close by her.
2
There was nothing so VERY remarkable in that; nor did Alice think it so VERY much
out of the way to hear the Rabbit say to itself, 'Oh dear! I shall be late!' (when
she thought it over afterwards, it occurred to her that she ought to have wondered
at this, but at the time it all seemed quite natural); but when the Rabbit actually
TOOK A WATCH OUT OF ITS WAISTCOAT-POCKET, and looked at it, and then hurried on,
Alice started to her feet, for it flashed across her mind that she had never before
seen a rabbit with either a waistcoat-pocket, or a watch to take out of it, and
burning with curiosity, she ran across the field after it, and fortunately was just
in time to see it pop down a large rabbit-hole under the hedge.
```

Figure 6 Sentence concordance for *rabbit* in *Alice in Wonderland*

There are advantages and disadvantages to this kind of display, but in the early stages of introducing concordancing to learners and other students of language it is sometimes the case that a sentence view of concordance data can be more useful than the KWIC display, as it presents fewer reading challenges to newcomers to corpus analysis.

Word Forms and Lemmas

The first concordance examples discussed in this entry were for single word forms. While such searches can be very revealing, there are times when a researcher needs to move beyond individual word forms. In such cases it can be important to be able to investigate a *lemma* instead. Sinclair defines *lemma* as follows:

A lemma is what we normally mean by a “word.” Many words in English have several actual word-forms—so that, for example, the verb *to give* has the forms *give*, *gives*, *given*, *gave*, *giving*, and *to give*. In other languages, the range of forms can be ten or more, and even hundreds. So “the word *give*” can mean either (i) the four letters **g, i, v, e**, or (ii) the six forms listed above.

In linguistics and lexicography we have to keep these meanings separate; otherwise it would not be possible to understand a sentence like “*Give* occurs 50 times in this text.” For this reason, the composite set of word-forms is called the lemma. (Sinclair, 1991, p. 173)

In other contexts, researchers may need to search for particular phrases (fixed combinations of word forms) which have importance for them, or even to search for noncontiguous patterns where the node is separated from a list of required context words by a set span of word forms or characters. Modern concordancing software offers resources which make

both of these tasks relatively straightforward. With an unmarked-up corpus (i.e., one that does not contain part-of-speech [POS] tags, lemma information, or other codes), two strategies can be used. The first requires the user to enter a list of the word forms which constitute the lemma of a stem, for example *cat/cats* or *smile/smiles/smiling/smiled*. A concordance for *cat/cats* in *Alice in Wonderland* will look like Figure 7.

```

N
1      ht, I should think!' (Dinah was the cat.) 'I hope they'll remember her
2      very like a mouse, you know. But do cats eat bats, I wonder?' And here

10     inah: I think you'd take a fancy to cats if you could only see her. Sh

```

Figure 7 Concordance sample for *cat/cats* in *Alice in Wonderland*

An alternative approach to typing all the word forms you wish to find is to use the *wild-card* facility (*regular expression* in Unix environments) which different concordancing programs offer. A wild card is a symbol which can be used to stand for one or many alphanumeric characters. In a Windows operating system environment, wild cards might include examples such as those in Figure 8.

wildcard	search	result
* any character at the end of a word (including punctuation)	cat*	I'm afraid, but you might catch a bat, and that's a mouse, you know. Figure 8 Concordance sample from *Alice in Wonderland* using Windows wild cards

Phrases

Concordancing software does not restrict you to searching for individual word forms. It is also possible to look for closed and open phrase patterns, using a mix of full word forms and wild cards to create search algorithms that most closely meet your needs. Thus, in a corpus of business correspondence a search for *thank you for* produced the results shown in Figure 9.

Figure 10 Concordance sample using a wild-card phrase search

In a larger corpus, it begins to be possible to search for quite extended patterns and obtain a surprisingly large number of results. Thus a search in the 100-million-word British National Corpus (BNC) (Oxford University Computer Service, 1995) for *if * * * enough to* produces 156 results. (In the example in Figure 11 the contracted word form *hasn't* counts as one word. This is a feature common to most concordancing programs.)

Working with Corpus Data

Searching for words or phrases in a small corpus is simple enough. However, as the corpus size increases so do the problems of managing the data which searches will produce. Three main ways of dealing with data overload are sorting, sampling, and restricted searches.

By taking advantage of the fact that your concordance is electronic, you can *sort* output so that like is grouped with like. There are at least three ways of re-sorting concordance data: by the node word itself, by the left context of the node, and by the right context. Of course, sorting can be done in ascending or descending order. If further information is available, the data can also be sorted by text, by tag, or by any other available category. The three examples for the search string *look** in Figures 12–14 demonstrate the potential for this approach.

A search for *look** in Lewis Carroll's *Through the Looking Glass* produces 155 results. This is not a huge amount of data, but it is still more than you can take in without some further processing. Sorting the node word first reveals which form of *look** occurs most frequently (*looking* with 71 occurrences) and which form is least frequent (in this instance *looks*, which only occurs once) (see Figure 12).

```

145   the crown, NOW!' the Unicorn said, looking slyly up at the crown, whi

Sorting by the left context shows us, for example, the typical subjects for *look** as verb (see Figure 13).

```

1      d pretended not to see it: but it looked a LITTLE ashamed of itself,
2      d it round for him. 'I thought it looked a little queer. As I was say
3      to carve a joint before. 'You look a little shy; let me introduce
4      on't understand,' the Knight said, looking a little vexed. 'That's wh
5      an't get at me!' Then she began looking about, and noticed that wha

10     n wool. Alice rubbed her eyes, and looked again. She couldn't make out

```

Figure 13 Concordance sample for *look** sorted by the left context in *Through the Looking Glass*

8 CONCORDANCING

Sorting by the right context can show typical collocating adverbs, prepositions, complements, and so forth (see Figure 14).

```
1      d pretended not to see it: but it looked a LITTLE ashamed of itself,
2      d it round for him. 'I thought it looked a little queer. As I was say
3          to carve a joint before. 'You look a little shy; let me introduce
4      on't understand,' the Knight said, looking a little vexed. 'That's wh
5          an't get at me!' Then she began looking about, and noticed that wha
6      caught the shawl as she spoke, and looked about for the owner: in ano
7      What AM I to do?' exclaimed Alice, looking about in great perplexity,
8          'Don't tease so,' said Alice, looking about in vain to see where
9          away at full speed. Alice stood looking after it, almost ready to c
10     n wool. Alice rubbed her eyes, and looked again. She couldn't make out
```

Figure 14 Concordance sample for *look** sorted by the right context in *Through the Looking Glass*

Depending on the software you are working with, sorts can also extend beyond the immediate context of the node, with sorts at one, two, three, or more words to the right or left of the node being possible.

If you are still overloaded with data from a concordance search, you can either reduce the amount of text that you are working with, or use computer software to make a randomized selection or *sample* from the data. A final way of reducing the data generated by your search, if your concordancing software permits this, is to build *restricted searches*. With a POS-tagged corpus such as the BNC, it is possible to specify the word classes that will be included in a search (Aston & Burnard, 1998). Thus, rather than looking for, say, *rabbit* (2,571 results in the BNC), it would be possible to look for *rabbit* as *verb* only (39 results). However, even if you do not have a POS-tagged corpus, it is possible to develop simple search algorithms by making use of the features that most modern concordancing programs provide, which will greatly improve the searches that you make.

For example, in academic discourse, the ways in which extended noun phrases are post-modified is an important component in the construction of meaning in impersonal, fact-oriented written texts (Biber, 2006). Assuming you have access to a corpus of experimental science research journal articles which have not been POS tagged, how do you go about collecting examples of, for instance, extended noun phrases in grammatical subject or sentence theme position for research or teaching purposes?

If you have access to a concordancer which uses an asterisk (*) as a whole- or part-word wild card, it is possible to make the following search algorithm:

*Search for "the * of" in the context of "*" up to four words to the right*
(i.e., search for any word preceded by a definite article and followed by the preposition *of* in the context of a preceding full stop up to four word forms to the right of the node)

This produced results such as those in Figure 15 (shown in sentence concordance format with extended theme in bold and node underlined).

```
1      To determine the significance of these banding patterns following the MEE  
      analysis of samples of pools of individuals we compared individual worms  
      with the pools using the rational and allozyme interpretation as detailed by  
      Andrews and Chilton (1999).  
2      The usefulness of the application of MEE to provide answers to parasite  
      systematics has been reviewed by Andrews and Chilton (1999).  
3      To date, the roles of genetic variation of O. viverrini on this observed  
      variability in infection, transmission and associated disease are not known.  
5      The specificity of this PCR, in addition to its sensitivity (50 pg),  
      demonstrates its usefulness in Leishmania typing.
```

Figure 15 Concordance sample for *the * of* in a text from *Acta Tropica* (retrieved January 4, 2010 from <http://www.sciencedirect.com/science/journal/0001706X>)

Further refinements of this simple algorithm can be devised, making it possible to identify, quantify, and describe other kinds of noun post-modification (present or past participle, relative clause, and other prepositional phrases), and, of course, it is then possible to devise other searches to identify other lexicogrammatical or discourse features.

Conference Interpreting

SYLVIA KALINA

Conference interpreting (CI) is the mediation, from a source language (SL) into a target language (TL), of speeches, presentations, and spontaneous comments by delegates and participants at international conferences where people do not speak the same language. Today it is mostly done in the simultaneous mode: interpreters work in soundproof booths and delegates listen to their output through headphones. As opposed to some other types of interpreting (e.g., community settings), interpreters are not expected to perform any intercultural mediation apart from offering explanations of names, acronyms, or institutions that are indigenous to the culture of the speaker. Conference interpreters work either unidirectionally from one or several languages into their native tongue (A-language), or bidirectionally between their A-language and a B-language which they speak nearly as well as their native tongue.

From a Profession to a Discipline

In the late 19th and the 20th century—and especially after World War II—the number of international and multilingual conferences began to rise sharply, and the profession of conference interpreting developed in conjunction with the corresponding demand for oral linguistic mediation. Initially, conferences were interpreted in the consecutive mode: that is, an entire speech or intervention was made, and the TL version followed afterward. For this mode of CI, memory and note taking are the most important skills. As soon as technological progress had produced the appropriate transmission equipment, the simultaneous mode became predominant, especially where many languages are concerned, as it does not result in loss of time for translation. The profession of CI is a highly respected expert activity. Today, it is practiced either by freelancers or by salaried employees in a multilateral setting, for example within international organizations (IO). Conference interpreters have developed a high professional profile, and have a worldwide professional association, the International Association of Conference Interpreters (AIIC, Association Internationale des Interprètes de Conférence).

After an early period where it was linguists who took a scientific interest in CI (see Gerver, 1976), professional interpreters themselves started researching into what they practiced. Seleskovitch (1978) based her model of human comprehension on sense (meaning), whereas the wording (form) can be neglected: “languages do not choose the same set of words to point to the same objects or concepts so that speakers in individual languages do not use the same words to express the same ideas” (1978, p. 337). According to Seleskovitch, good interpreting quality is obtained if the interpreter works into his or her mother tongue and has an excellent understanding of source language as well as extensive general world knowledge.

Although more informal types of interpreting had been practiced much earlier, it was only with the emergence of CI that people began to reflect on interpreting: researchers wanted to know whether and—if so—how a person can listen in one language and speak, that is, translate, in another at the same time. Linguistic research initially focused on the use of speakers’ pauses by simultaneous interpreters, modifications of grammatical structure

in the TL, and types of errors identified in the interpreting product. The contributions of interpreting professionals dealt with the processes of consecutive and simultaneous interpreting as such, the cognitive processes involved, and the specific constraints particularly in simultaneous interpreting (SI).

In the early research periods it was found that the quality of CI required spontaneous speech production by conference speakers, as only ideas that were verbalized on the spur of the moment could be translated immediately in the oral mode, with interpreters using strategies such as analysis and segmentation of source text, anticipation, paraphrasing and, occasionally, generalizing. Meanwhile, CI is practiced even with carefully prepared and complex source texts read at maximum speed, as speakers are constrained by limits of speaking time. Conference interpreters have had to adapt to these conditions, and have developed appropriate skills and strategies.

The present state of the art in CI research (now known as “interpreting studies,” a term that also includes other types of interpreting) is impressive. It extends from models that seek to explain mental processes by studying errors and identifying process-specific error types (Jensen, 1985), and concerns itself with the typical features of prosody in simultaneous presentation (Shlesinger, 1994; Ahrens, 2005). Researchers are also investigating cognitive processes involved in the act of interpreting (Gile, 1995; Setton, 1999; Moser-Mercer, 2000), as well as strategies used by interpreters to cope with the typical deficiencies of the mediated communication process (Kohn & Kalina, 1996). Furthermore, research is being carried out into user preferences (Kurz, 1989; Moser, 1996), cultural aspects of interpreting (Pöschhacker, 1994), analyses of quality and its assurance (Kopczyński, 1994; Kalina, 2005), to mention only a few areas.

Research methodology has also advanced. Earlier comparisons of source and target texts were based on written transcripts of experimentally obtained versions; today, product analysis is performed on the basis of authentic audio or video recordings of real-life speeches and interpretations, and cognitive processes are studied with sophisticated experimental methods.

After CI research results started to be discussed by the scientific community and professionals, research into other modes of interpreting in the fields of public service, court, police, and medical dialogue interpreting was taken up. The analysis of different settings and their impact on interpreting approaches and techniques brought CI and other interpreting types more closely together so that we can now speak of a discipline of interpreting studies which is concerned with all types of interpreting.

CI as Comprehension and Production of Speech

Processes during consecutive CI are rather similar to those of more informal dialogue interpreting, with two distinctive features. One is that cultural mediation is less relevant as audiences at international conferences are largely aware of intercultural differences, and the other is that longer speech segments are usually processed (in the heyday of consecutive interpreting, speeches of about 20 minutes and sometimes up to an hour and more used to be rendered integrally, with every nuance and detail of the original contained in the interpreted version). Today, sections of speech that are interpreted tend to be kept much shorter so that listeners do not have to wait too long before receiving the translation. Also, this helps make an event more interactive, as the audience can respond more spontaneously.

In SI, the incoming sound has to be of excellent quality. Interpreters have to cope with all types of speakers, who may speak in a language which is not their native language, or may wish not to commit themselves, and are rarely aware of interpreting constraints. SI

is practiced not only at international conferences such as the meetings of the European Parliament with its 23 languages, and other international organizations, but also at bilingual events (scientific symposia, training seminars, interviews, international works council meetings, legal depositions, etc.), and for the media.

Where technical facilities are not available and only one or two participants need interpretation, whispering may be practiced. This mode is even more stressful than SI proper, as interpreters have to speak with subdued voice—not really whispering—and at the same time concentrate on input despite noise levels in the conference room.

In SI, one of the most interesting research questions continues to be that of interpreters' *décalage* (ear–voice span). This is not a fixed time span to be recommended or maintained; rather, the time which elapses until an interpreter starts to verbalize an idea of the original she or he has understood may vary as a function of the interpreter's knowledge about speaker and subject, semantic complexity of the original, and structural similarities or dissimilarities between languages.

SI takes place in adverse conditions, inasmuch as interpreters perform dual and competing cognitive activities—listening to a speech segment in one language, analyzing it, and at the same time producing another segment in another language (Gile, 1995)—and do not have control over semantic content and processing speed. As incoming discourse remains “in the ear” when TL text is produced, CI is extremely prone to performance errors (Kohn & Kalina, 1996). Complex figures which are unproblematic to the translator constitute a real challenge to interpreters: enumerations of items have to be processed very fast so that every item is remembered; presentation rate (speaking speed) has to be adapted and modified during the whole process; and items that are not properly understood have to be either deleted (left out) or rendered in a more generalized form. Anticipation (probabilistic prognosis, see Chernov, 1994) is an important strategy in SI, especially regarding languages with different syntactical structures. In addition to listening to the original speech (source text) and producing their output (target text) at the same time, interpreters have to monitor their own speech production. Due to the adverse processing conditions, the target text may frequently contain speaking errors (false starts, hesitations, filled pauses, etc.). Depending on the remaining processing capacity, the decision may be to either correct an error or intentionally not correct it; in the worst case, where no capacity is left for the monitoring process, the interpreter may not even be aware of output errors.

New Technologies and CI

Despite a multitude of innovations in conference technology and for the interpreting booth, such as source text “repeat” functions or equipment for visually handicapped simultaneous interpreters, the cognitive effort interpreters need to put into the process has not diminished. Great hopes initially placed in machine interpreting (MI) have not materialized for the conference setting, so, for the time being, MI will not be a threat to human conference interpreters. However, working conditions before and during an assignment have been influenced both positively and negatively by new information and communication technologies, as the following list illustrates:

- Preparation is much easier with digital knowledge resources, the Internet, and quick access to all types of documents.
- With English being used more and more as a *lingua franca*, more non-native speakers with foreign accents make interpreters' work more difficult, and those conference interpreters who do not work from/into English see their languages being cut out of conferences.

- Media presentations often do not take interpreting requirements into account. When a video clip has background music or there is audible machine noise, it becomes more difficult for interpreters to follow what is being said.
- The technical facilities that now exist everywhere tend to make users see interpreting as part of an automated communication process and neglect the need for preparation and comprehension. Interpreters are regarded as part of the technical equipment. Users are not aware of their needs—for preparation, for example. The trend is toward hiring interpreters at the last moment and expecting them to act as ever-ready encyclopedias.
- Communication technologies allow for remote interpreting (RI), which may be cheaper but affects interpreting quality. RI risks turning CI even more into a service to be hired at the very last minute; furthermore, the atmosphere of a conference, which is also a source of information for interpreters, cannot be tapped into in the same way as when interpreters are physically present in the conference hall.
- Subjects negotiated at international level are becoming more and more complex, and interpreters have to be extremely versatile, covering one topic at a technical conference on one day and then another topic for the media on the next.

CI Training

CI is the only type of interpreting for which training was offered at university level from the outset. This greatly helped to develop the profession, and many experienced conference interpreters are teaching at universities around the world. Meanwhile, the theoretical components of translation and interpreting studies and of communication are firmly anchored in CI Masters' programs. With technological progress and new media applications, university training for CI is becoming more challenging and more demanding; on the other hand, students can be prepared for the market and its requirements much better than in the past. This is the result of better media equipment and electronic learning methods but also of the development of systematic training on the basis of proven theoretical approaches. As future developments in information and communication technology can hardly be predicted, it is all the more necessary to prepare the young generation of interpreters for present and future challenges.

Connectionism

PING LI AND XIAOWEI ZHAO

Connectionism, also known as parallel distributed processing (PDP) or artificial neural networks, is an important theoretical framework as well as a computational tool for the study of mind and behavior. Connectionism advocates that learning, representation, and processing are parallel, distributed, and interactive in nature. It argues for the emergence of human cognition as the outcome of large networks of interactive processing units operating simultaneously. Connectionism has had a profound impact on many areas of research including linguistics, psychology, and artificial intelligence, and language as a hallmark of human behavior has received in-depth treatment since the beginning of connectionist research. The acquisition of the English past tense, the recognition of speech, and the processing of sentences are among the earliest connectionist models (McClelland, Rumelhart, & the PDP Research Group, 1986). The application of connectionism to second language acquisition research, however, has only recently gathered momentum, as discussed in this entry.

Neural Basis

The development of connectionism was largely motivated by the idea that the human brain does not operate like a digital computer. The human brain consists of a huge network of nerve cells, indeed, with billions of interconnected neurons, for the purpose of information processing. At the individual neuronal level, the electro-chemical processes for information transmission are relatively simple, going from cell bodies to axons and passing through a synaptic cleft to reach the dendrites of another neuron. It is at the neuronal-network level that information processing becomes more interesting and also more complicated, given that a single neuron is usually connected to thousands of other neurons. The strengths of their synaptic connections (the effectiveness of signal transmission across synapses) are not fixed, and it is the changes in synaptic strength that determine the neuronal teamwork. The ability of the human brain to derive the “optimal” strengths for a neuronal network in solving any given problem is the basis of neural information processing that inspires connectionist theories of learning, memory, and language. Each individual neuron is not very powerful, but a simultaneously activated network of neurons makes human cognition possible.

Given the above picture of neural information processing, connectionist models are built on two fundamental components: simple processing elements (*units, nodes, or artificial neurons*), and connections among these processing elements (hence the term “connectionism”). Like real neurons, a node receives input from other nodes. The input signals are accumulated and further transformed via a mathematical function (e.g., a sigmoid function) to determine the activation value of the node. A given connectionist network can have varying numbers of nodes, with activations spreading from node to node via the corresponding connections, either within the same level or across levels. Like real synapses, the connections can have different levels of strength (*weights*), which can be adjusted according to learning algorithms (see below), thereby modulating the degree to which a source node can influence a target node. In this way, the network can develop unique combinations of

2 CONNECTIONISM

weights and activation patterns of nodes in representing (thus memorizing) different input patterns from the learning environment. Unlike computer programs that are dedicated to specific tasks and are fixed a priori, the weights and activation patterns in connectionist networks are continuously adapted during learning, and it is this adaptive process that makes connectionist networks interesting models of human behavior.

Learning Rules

Different connectionist networks use different algorithms to adjust weights to achieve learning. These algorithms can be classified roughly into two groups: supervised and unsupervised learning. A typical connectionist network with supervised learning consists of three layers of nodes: input layer, hidden layer, and output layer. The input layer receives information from input patterns (e.g., representations of alphabetic features), the output layer provides output patterns produced by the network (e.g., classifications of alphabets according to shapes), and the hidden layer forms the network's internal representations as a result of the network's learning (e.g., the visual similarities between "O" and "Q"). The most widely used supervised learning algorithm in psychological and cognitive studies is "backpropagation" (Rumelhart, Hinton, & Williams, 1986). According to backpropagation, each time the network learns an input-to-output mapping, the discrepancy (or error, δ) between the actual output (produced by the network based on the current connection weights) and the desired output (provided by the researcher) is calculated and is propagated back to the network so that the relevant connection weights can be changed relative to the amount of error ($\Delta\omega = \eta * \delta$, where $\Delta\omega$ indicates change of

Figure 1 A demonstration of SOM's training process

Note. When an input vector representing the meaning or sound of a word (e.g., "table") is sent to the network, a best matching unit (the black node) becomes highly active. Its weight vector and that of its neighboring units (the gray nodes) are adjusted proportionally, such that they become more similar to the input. The size of the neighborhood usually decreases as the training progresses, and eventually only the best-matching unit itself is included in the neighborhood.

weight, η the rate of learning, and δ the error). Continuous weight adjustments in this way lead the network to fine-tune its connection weights in response to regularities in the input-output relationships. At the end of learning, the network derives a set of weight values that allows it to take on any pattern in the input and produce the desired pattern in the output.

In contrast to the backpropagation algorithm, unsupervised learning uses no explicit error signal at the output level to adjust the weights. A popular unsupervised learning algorithm is the self-organizing map (or SOM; Kohonen, 2001), which consists of a two-dimensional topographic map for the organization of input representations, where each node is a unit on the map that receives input via the input-to-map connections. At each training step of SOM, an input pattern (e.g., the phonological or semantic information of a word) is randomly picked out and presented to the network, which activates many units on the map, initially randomly. The SOM algorithm starts out by identifying all the incoming connection weights to each and every unit on the map, and for each unit compares the combination of weights (weight vector) with the combination of values in the input pattern (input vector). If the unit's weight vector and the input vector are similar or identical by chance, the unit will receive the highest activation and is declared the winner (the best-matching unit, see Figure 1 for an example). Once a unit becomes highly active for a given input, its weight vector and that of its neighboring units are adjusted, such that they become more similar to the input and hence will respond to the same or similar inputs more strongly the next time. This process continues until all the input patterns elicit specific response units in the map. As a result of this self-organizing process, the statistical structure implicit in the input is captured by the topographic structure of the SOM and can be visualized on a 2-D map as meaningful clusters. Finally, although not an inherent property of SOM, different maps can be linked via adaptive connections trained with the Hebbian learning rule (Hebb, 1949), a neurally inspired and biologically plausible mechanism of associative learning and memory. The Hebbian learning rule can be expressed simply as $\Delta w_{kl} = \alpha_k \cdot \alpha_l$, where Δw_{kl} refers to change of weight from input k to l and α_k and α_l the associated activations, which indicates that the connection strengths between neurons k and l will be increased as a function of their concurrent activities (that is, neurons that fire together wire together).

Major Properties

Connectionism stands in stark contrast to the classical computational view of the human mind, which assumes that human cognitive operations have properties fundamentally similar to digital computers which rely on discrete (symbol-based), modular (domain-specific), and serial (one step at a time) processes (see Bates & Elman, 1993 for a review). First, in terms of knowledge representation, connectionism argues for "distributed representation": a given concept is represented not by a single discrete symbol as in classical cognitive models, but by multiple nodes and their weighted connections in concert, which leads to a distributed pattern of activation of relevant microfeatures. Because of distributed representation, one cannot directly identify crisp concepts or rules in a connectionist system, and therefore the acquisition of relevant concepts or rules entails the learning of appropriate activation patterns. As mentioned above, learning in connectionist networks can only be achieved by the adjustment of weights that hold among relevant processing units for appropriate activation patterns.

Second, connectionist theories assume a high degree of interactivity between various levels of information processing. Classical cognitive theories posit highly modularized symbolic subsystems. These modules are often "domain specific" and "informationally

encapsulated,” which means that they are designed to support specific cognitive processes and involve a low degree of interactivity (Fodor, 1983). If a module is damaged, the cognitive functions associated with it are all impaired. In contrast, connectionist networks depend crucially on information flow within and across different processing units and levels. Thus, even if parts of the system are damaged, the disruption of functions occurs only gradually, allowing for “graceful degradation” as seen in patients with brain injury of various types.

Third, although individual nodes in a network have limited power, just like individual neurons as discussed earlier, when multiple nodes are connected at any given time step of learning, they can process information simultaneously, giving rise to very powerful computational capacity in problem solving.

Finally, connectionist networks are nonlinear dynamical systems, capable of capturing nonlinear patterns often observed with children and adults during learning and development. This nonlinearity is introduced into the system by activation functions (e.g., sigmoid function) and certain topological structures in the network’s self-organization process (e.g., multiple layers, recurrent connections, and dynamic unit growth). Because of these properties, connectionist models are ideally suited to account for language acquisition in both the monolingual and the bilingual context, as we discuss in the next section. In classical symbolic models (e.g., Pinker, 1991), nonlinear patterns such as the U-shaped behavior are accounted for by a combination of multiple linear mechanisms (e.g., rules versus associations in the acquisition of the English past tense). By contrast, connectionism conceptualizes human behaviors as fundamentally nonlinear, emergent properties. Connectionist models can be considered close allies of the broader class dynamical systems (Spencer, Thomas, & McClelland, 2009), in which complex dynamic interactions among multiple features in the learning environment and multiple variables that characterize the learner determine the shape and outcome of the learning/representation system. This perspective has led to recent interests in constructivist neural networks, in which internal representations (i.e., the hidden units) are allowed to dynamically increase or decrease as a result of learning experience or task difficulty (see Shultz, 2003; Ruh & Westermann, 2009).

Connectionist Second Language Learning

Connectionist networks have been used to account for a wide range of important empirical phenomena in linguistic behavior, such as speech perception, speech production, semantic representation, reading acquisition, and language acquisition (see Westermann, Ruh, & Plunkett, 2009 for a review of connectionist language acquisition). Many of these studies have been based on the *simple recurrent network* (SRN), a model that clearly demonstrates language as a dynamical system (Elman, 1990). The SRN combines the classical three-layer backpropagation learning with a recurrent layer of context units. These units keep track of hidden-unit activations at a prior time point, which are then provided along with new input to the current stage of learning (hence “recurrent” connections). This method enables connectionist networks to effectively capture the temporal order of information, since the context units serve as a dynamic memory buffer of the system. Given that language unfolds over time, the SRN therefore provides a simple but powerful mechanism to identify structural constraints in continuous streams of linguistic input.

The utility of the SRN for language acquisition was quickly demonstrated in not only the monolingual context but also second language acquisition and bilingualism. French (1998) presented an SRN model of bilingual language processing that learns artificially generated sentences of the N-V-N structure in English and French. The network was exposed to mixed bilingual input, with the two languages intermixed at the sentence level. Its task was to predict the next word, given the current input in the sentence. French

showed that distinct patterns of the two languages emerged after connectionist learning: words from the two languages became separated in space according to a hierarchical cluster analysis of the hidden-unit activations. The model provided support to the hypothesis that the bilingual input itself is sufficient for the development of distinct mental representation of each language, without invoking separate processing mechanisms for different languages.

Along the same line, Zhao and Li (2007, 2010) further studied the development of bilingual speakers' lexical representation based on a model called DevLex (*Developmental Lexicon*). Unlike previous connectionist language acquisition models, DevLex and DevLex-II models are a set of large-scale multilayered, unsupervised, SOM-based models of language development (Li, Farkas, & MacWhinney, 2004; Li, Zhao & MacWhinney, 2007). The DevLex-II model was originally developed to capture first-language acquisition phenomena such as vocabulary spurt and lexical confusion (Li, Zhao, & MacWhinney, 2007). It includes three SOM maps responsible for representing the phonological content, semantic content, and output sequence of the lexicon, respectively. Through self-organization principles and Hebbian learning (see discussion above under Learning Rules), DevLex-II simulates word comprehension via phonology-to-meaning links and word production via meaning-to-sequence links. The model was trained to learn 1,000 English and Chinese words, with different onset times for the learning of the second language (L2, either English or Chinese) relative to that of the first language (L1, either Chinese or English). Our modeling results indicate that when the learning of L2 is early relative to that of L1, functionally distinct lexical representations may be established for both languages. This finding is similar to that of French (1998). However, when the learning of L2 is significantly delayed relative to that of L1, the structural consolidation of the L1 lexicon prevents the L2 from establishing distinct and independent lexical representations.

The findings from DevLex-II provide a computational account of the age of acquisition effect by reference to the dynamic interaction and competition between the two languages (see Li, 2009, for review and discussion). Instead of using age (and the maturational changes that accompany age) as the basis of the critical or sensitive period of language acquisition, our model points to the cascading effects of learning across developmental times as the explanatory mechanism underlying critical-period effects. The reduced plasticity in L2 learning could be seen as the result of structural changes due to the learning system's experience with L1, in that L1 consolidation adversely impacts the system's ability to reorganize and restructure L2 relative to L1. Consistent with this idea, a recent modeling work by Richardson and Thomas (2008) systematically evaluated the conditions under which critical-period effects may be observed in a SOM-based neural network. Their simulations suggest that the emergence of critical periods depends on a range of factors, such as representational resources, organizational structure, learning parameters, and the similarities between early and late training sets. When the new knowledge and old knowledge are similar, their model shows smaller critical-period effects; when the two are sufficiently different, the effects are more salient.

Conclusion

It has become increasingly clear that language can no longer be studied as an abstract innate mental entity as has been traditionally advocated (Chomsky, 1988). Connectionism argues in favor of a computational approach to the complexities associated with the dynamical interactions of the learning system with the linguistic environment (MacWhinney, 2001). The idea that complex human linguistic behavior can emerge from simple neurochemical processes may appear at first implausible, but connectionism has demonstrated that this is not only biologically plausible but also psychologically real: parallel distributed

information processing carried out by large-scale networks of interconnected neurons can account for the form–meaning mapping process in speech perception and speech production, as well as in language acquisition. In this perspective, we can consider rules of language as the product of neural network processes in the long human evolutionary history, in much the same way as a hexagonal structure emerges from simple acts of honeybees packing small amounts of honey into the honeycomb from multiple directions (Bates, 1984). Learning of a second language entails complex cognitive and linguistic constraints and interactions, and connectionist models provide insights into how these constraints and interactions may be realized in the natural learning context.

Connectives

MARINA BONDI

Connectives (or *connectors*) (French *connectif/connecteur*, Italian *connettivo/connettore*, Spanish *conector*, German *Konnektor/Konnektiv*) are a key feature of language in use and have been studied from many different points of view—syntactic, semantic, pragmatic, and cognitive. Connectives can be preliminarily defined as language elements whose main function is to connect utterances or text units, linking prior and subsequent information. Realized prototypically by conjunctions (*and*, *but*, *if*), they may be seen to cut across the whole spectrum of word combinations, including prepositional phrases (*in addition*), adverbials (*furthermore*), and clauses (*what's more*). Connectives can thus be studied both as functional sentence elements and as elements of a textual or discourse grammar. At sentence level, they connect words, phrases, or clauses. On the level of text and discourse, they may be seen to express or establish semantic or pragmatic relations between textual or discourse units.

Different approaches to connectives direct attention to different aspects, ranging from meaning relations to interactional aspects and cognitive features, argumentational value, language change, and cross-cultural elements.

The word *connective* owes much to the related notion of “logical” or “truth-functional” connectives (or operators) in logic and formal languages. Logical connectives are a set of expressions acting as truth functions. Examples would be: *and* (expressing conjunction), *or* (inclusive or exclusive disjunction), *implies* (implication), *if . . . then* (implication), *if and only if* (equivalence), and so forth. In formal languages, they can be represented by unambiguous symbols: conjunction ($\wedge$ or $\&$), disjunction ($\vee$), material implication ($\rightarrow$), and biconditional ($\leftrightarrow$, $\equiv$, or $=$). In natural language, the relations they represent are not limited to connecting propositions and are typically realized by a wide range of expressions.

In applied language studies, the interest in this wide class of units originates from the development of textual grammars and discourse analytic approaches in the 1970s and 1980s. With the notions of text and discourse, attention is brought to those very language elements—such as connectives or pronouns—that cannot be explained simply within the boundaries of the sentence. The study of textual cohesion and coherence looks at elements that reach beyond traditional grammar units like the clause or the sentence (Halliday & Hasan, 1976; van Dijk, 1977; Ducrot, 1980; Roulet, Auchlin, Moeschler, Rubattel, & Schelling, 1985). Halliday and Hasan's study on cohesion (1976), in particular, has been very influential in establishing an interest in connectives as giving “texture,” or unity, to texts. An extensive section is devoted to conjunction, where a set of disparate grammatical categories are identified as “*connectors*,” that is, expressions that link clauses or sentences to each other in discourse.

Pointing to a text-functional semantics, Halliday and Hasan's definition of cohesion concerns discourse relations above grammatical structure, thus excluding coordination and subordination. Conjunction is classified according to the semantic relations established by connectors into four main types, related to four main notions: addition (including additive and alternative relations, as well as exemplification and comparison), contrast (ranging from adversative “proper” to contrast, correction, and dismissal), causality (including cause, means, purpose, condition, and respective relations), and temporality (including successive and simultaneous relations) (Halliday & Hasan, 1976, pp. 238–66).

Later developments of systemic functional linguistics confirm a view of cohesion as discourse semantics, that is, meaning beyond the clause. The basic relations are still described as “four kinds of logic” or “logical relations” in recent models of analysis (e.g., Martin & Rose, 2003, pp. 110–12). Some degree of consistency in spelling out the types of relations expressed may also be found in other approaches.

Approaches such as rhetorical structure theory have also paid great attention to the relations established between discourse units and produced systematic mappings of discourse relations. Their interest, however, lies more in the relations themselves than in the lexicogrammatical signals.

The wide array of formal realizations of the elements that are used in actual discourse to connect textual units makes it impossible to say they meet certain syntactic criteria. Most approaches recognize at least three sources: conjunction, adverbs, and prepositional phrases (e.g., Fraser, 1999, p. 943). The reason for choosing a connective is obviously semantic—the relation that needs to be expressed (e.g., “cause”)—but the choice of a grammatical structure is also important from a textual point of view: a subordinate clause will help treat the two units (e.g., cause and effect) as a single idea, whereas coordination will present the two units as equally important. Separate sentences might also be linked by sentence adverbs or other connectors. The order of elements can be the determining factor in explaining the choice of one form or another, especially in as far as word order contributes to information (given new) structures.

It should be noticed, however, that connectors are multifunctional and a single connective can express different kinds of meanings. A conjunction like *and*, for example, can be used to indicate addition (“American historian-autobiographers have usually been unaware of each other’s publications, *and* they do not refer to any common theoretical framework”), cause/condition (“Subscribe *and* get 4 issues free”), and time sequence (“When a massive star runs out of fuel at the end of its life, it collapses *and* explodes”).

When considering the “linking system” as a whole, it is important also to consider implicit connections, that is, links that are not marked explicitly. We can think of a zero-realization or nonrealization of connectives (see also Lenker & Meurman-Solin, 2007). In “Subscribe. Get 4 issues free” the conditional meaning would be still inferable from the context.

The category of connectives, on the whole, seems to blur the distinction between grammatical words like *and* or *but* and lexical patterns like *in addition to that* or *what’s more*. It is possible to say with Aijmer (2002, pp. 16–19) that even when they originate in complex lexical patterns, connectives—like most pragmatic markers—can be treated as distinct from most lexical items: they are somewhat “grammaticalized” (Hopper & Traugott, 1993) through time—they become more constrained morphosyntactically and function as indivisible units. The process can be illustrated diachronically through the change from clause-internal adverbial to sentence adverbial and discourse marker, as shown, for example, by Schwenter and Traugott (2000) in the case of *in deed* becoming *indeed*, epistemic sentence adverb and marker of elaboration or clarification.

Connectives are seen as relational and organizational units from a textual and pragmatic point of view, acting as instructions for the reader/hearer in many cognitive or semantic approaches. The nature and scope of the relations, as well as the multifunctionality of connectors in general, are not clearly agreed upon in the literature. The class itself is more often defined in terms of a core and periphery (Pons Bordería, 2008) rather than in terms of necessary and sufficient conditions. Items assume different degrees of connectivity and can be shown to have many other functions.

The textual perspectives developed by text linguistics and discourse analysis have also inspired studies on discourse production and comprehension. One of the most interesting areas in focus has been that of metadiscourse, discourse about the evolving discourse.

Connectives are presented as one of the main categories of metadiscourse already in Vande Kopple's classification system (1985), where they are clearly identified as part of textual metadiscourse, showing the connection between parts of a text, whereas in Crismore, Markkanen, and Steffensen (1993) "logical connectives" are limited to coordination of main clauses. Later models (e.g., Hyland, 2005) show increasing awareness of the multifunctional nature of connectives, while also clarifying that the status of connective does not in itself guarantee metadiscursive status (Ädel, 2006, p. 22).

Terminological Debate

The debate on connectives is complicated by terminological instability and by the complexity of the relations of these elements of textual grammar with the rapidly developing fields of semantics and pragmatics. The terminological debate is clearly related to the centrality of connectives in text organization, production, and comprehension, as well as to their inextricable link with different approaches to grammar, semantics, pragmatics, and cognition.

Problems arise soon in differentiating "connectors" (Halliday & Hasan, 1976), "discourse connectives" (Blakemore, 1987), and "discourse markers" (Schiffrin, 1987), and later also "pragmatic markers" (Aijmer, 2002), "discourse particles" (Fischer, 2006) or—in the German tradition—"pragmatic particles." Discourse markers are sometimes almost identified with connectives as defined above. Fraser, for example, calls discourse markers those elements that signal "a sequential relationship between the current basic message and the previous discourse" (Fraser, 1990, p. 383), or that "function like a two-place relation" (Fraser, 1999, p. 938), while excluding other pragmatic markers such as commentary markers, focus particles, and so forth. The relations expressed can refer to discourse units, as well as topics, and their basic meanings recall other definitions of connective relations (elaboration, contrast, inference, or temporality). Other linguists refer to discourse markers as a hyperonymic class of elements including connectives, modal particles, interactive markers, and so forth (e.g., Pons Bordería, 2008). Some look at connectives and discourse markers as a complementary class of markers, expressing respectively relations between units and modal relationships between the speaker and the message.

In general, when a distinction is made, or when the word "connective" is used to indicate the field in focus, the interest is on the connecting, coherence-establishing function of elements. Connectives are found in both written and spoken utterances; they tend, however, to be variously integrated into the discourse and to involve different "conversational" aspects such as topics or activities (Fischer, 2006, pp. 8–11). This will normally mean that there is the need to provide a picture of connectives that should be consistent with both the general field of discourse or pragmatic markers and long-standing grammatical analyses of conjunction within and between sentences. The need to integrate syntactic, semantic, and pragmatic analysis seems to be central to many different theoretical frameworks (Celle, 2007).

Semantics and Pragmatics: Multifunctionality of Connectives

Studies of connectives have often highlighted the problems of distinguishing semantic from pragmatic meaning in their use (Halliday & Hasan, 1976; Schiffrin, 1987; Fraser, 1990, 1999). Given the range of elements included and the complexity of semantic and pragmatic functions, attempts to arrive at a functional typology or to provide an account of meaning relationships have been accompanied by an awareness that categories may be overlapping and that many connective elements may have different functions at the same time.

One of the first issues of debate raised in the study of connectives is the nature of the relation expressed on the semantic and pragmatic levels. The distinction between external

and internal conjunction, introduced by Halliday and Hasan (1976), is particularly clear in some areas of meaning. Temporal conjunction, for example, may easily distinguish relations between events talked about, as expressed by time adverbials in a narrative (*then, previously, meanwhile*), and relations between parts of a text, as in enumeration (*firstly, secondly, finally*). Additional relations, on the other hand, can be very fuzzy from this point of view and signal a relation that works both at the level of the experience represented in discourse and in the development of discourse, as in the following statement supported by two arguments “These editions are valuable, but they have their limitations. . . . They cover only parliaments, not conventions of estates. *And* they contain errors and omissions.” Most approaches to connectives, however, tend to distinguish the two functions—organizing the experience represented in a discourse sequence and organizing discourse as such.

Ducrot (1980, p. 16) adds an “enunciative” perspective, while looking at two different types of *mais* (‘but’), those expressing a contrastive meaning that derives from “facts,” and those contrasting speech acts. Ducrot’s work introduces two elements that will have fruitful developments in semantics: an instructional view of meaning and a study of implicit meanings. Connectors are seen as linking language units and giving readers/hearers instructions on how to interpret the relation between the semantic units connected.

Schiffrin (1987) studies the relationship signaled by *but* in terms of both ideational (referential, derived from “facts”) and interactional content and establishes a model that looks at three types of structure: ideational content, verbal action, and exchange structure. Her study of *but*, for example, distinguishes its use for referential contrast, functional contrast, and contrastive actions, that is, “speakers’ efforts to make a point in reaction to interruptions, distractions, challenges, and disagreements” (Schiffrin, 1987, p. 177). She concludes that the semantic meaning of *but* is contrastiveness and the pragmatic meaning is speaker-return, which has an expressive function of point making, but she also admits that the connector can mark all of three types of contrast simultaneously.

In relevance theory (and related cognitive approaches) connectives are defined in a strict sense, as elements that constrain the inferences that can be derived between two propositions (Blakemore, 1987). Attention is thus paid to the reader/hearer’s perspective, rather than to the text itself. Debate originates from the distinction between conceptual elements (words encoding a concept, information about the conceptual representations to be derived from a proposition) and procedural elements (instructions regarding how to process a concept) (Wilson & Sperber, 1993, p. 2). Connectives are identified as procedural elements, encoding procedural constraints on the inferential phase of comprehension (Blakemore, 1987; Wilson & Sperber, 1993, pp. 19–21).

The distinction between procedural and conceptual has recently been presented as gradable, with connectors expressing different degrees of strength of conceptual and procedural coding (Moeschler, 2002, p. 277), while maintaining the function of linking mental representations of experience, sequencing them, and making explicit the relation between them.

Pragmatic interest in different degrees of explicitness/implicitness in utterances is reflected in many approaches. Fraser (1990, 1999), for example, while focusing more explicitly on a grammatical-pragmatic perspective and looking at discourse markers as signals of the relations between the utterance preceded and followed by the signal, also shifts the emphasis from the speaker to the hearer’s interpretative activity. The hearer has to find whether the relation expressed is with the direct message of the previous textual segment or with any of the implicit meanings realized, whether implicit assumptions, logical implications, or conversational implicature.

Studies of individual connectives have also often debated the issue of their “core meaning,” variously emphasizing the functional role of connectives, to be seen as instructions for interpretation (Aijmer, 2002), or their invariant semantic properties (Rossari, 2000).

The picture of multifunctional units is further complicated when attention is paid to the multifarious nature of the units related by connectives. What exactly do connectives connect? On the one hand they may be seen to designate the relationship between propositional units or mental representations of experience. On the other hand, they may connect a wide range of elements in discourse (Schiffrin, 1987). Rehbein, Hohenstein, and Pietsch (2007, p. 4) identify a long list of “dimensions” that can become either the starting point or the target point of a connective: the constellation (speech situation), the utterance act, the illocutionary act, the propositional act, knowledge, other mental processes (e.g., evaluation, planning, etc.), and cooperation (interaction-management).

A Range of Perspectives

In a discourse perspective, Roulet et al. (1985) use “connecteurs” to refer to markers of the structure of discourse and group them according to their argumentative functions: argumentative, counter-argumentative, consecutive, and reevaluative. The study of connectors proves to be an interesting area of convergence of discourse analysis and argumentation studies. *L’argumentation dans la langue* (*Argumentation in language*) (Anscombe & Ducrot, 1983), in particular, has a special interest in the topic and aims at discovering argumentative instructions in connectors. The approach shows for example that some contrastive relations can best be explained with reference to the argumentative dimension of some common or shared knowledge called *topos*, which is part of our stereotyped encyclopedic knowledge and is shared by speakers of a language, as well as those sharing the same culture or way of thinking.

More recently, a growing body of studies has been based on the analysis of corpora, that is, principled collections of authentic instances of language in use. Corpus work has introduced further descriptive possibilities and interest in both diachronic (see, for example, Lenker & Meurman-Solin, 2007, for a range of approaches) and synchronic perspectives (Aijmer, 2002). Corpus-based analyses can complement more intensive studies of particular texts, and vice versa. Text and discourse studies can be built upon when closer analysis of particular instances of communicative events is integrated with quantitative data from wider textual bases. These provide the necessary background and support to textual interpretation, for example, by analyzing co-occurrence patterns that characterize specific genres or texts, or diachronic interpretation, for example, tracing the path to grammaticalization.

Distributional patterns across registers are analyzed, for example, in Biber, Johansson, Leech, Conrad, and Finegan (1999), under the headings of linking adverbials, coordinators, and subordinators. Quantitative analysis shows, for example, that linking adverbials are “considerably more common in conversation and academic prose than in fiction and news” (p. 880). Information is also offered on the semantic categories that characterize different registers or genres, showing, for instance, that academic prose is distinguished by intensive use of enumerative/additive/summative adverbials, while news presents the lowest level of contrastive/concessive adverbials.

Diachronic studies, on the other hand, look at connectives from the point of view of language change. Descriptive work focuses on the development of individual connectives or types of connectives, such as relative pronouns, time adverbials, or concessive connectives in general (Lenker & Meurman-Solin, 2007).

Crosslinguistic analysis is also becoming prominent in the field. It is concerned with establishing correspondences across languages, while often aiming at tackling typological questions and finding discourse universals. Connectives may operate at several linguistic levels, often showing that the same function is expressed lexically in one language and grammatically in another. Complete equivalence, however, is not the rule. The study of

parallel translation corpora can contribute to giving a picture of the multifunctionality of connectors, as well as to establishing a network of semantic relations between them in terms of their closeness to or remoteness from each other in the semantic space (Dyvik, 1998). The integration of functional and formal perspectives in the study of a wider semantic field is often regarded as more reliable and more rewarding than research based on a single language (Aijmer & Simon-Vandenberg, 2004).

The empirical study of non-native-speaker language is adding a further perspective to applied studies on connectors (see Granger & Tyson, 1996, for an early example). Muller (2005) reviews the relation of a range of applied interests to the study of connectors: second language acquisition, communicative competence, interlanguage pragmatics, and the study of learner corpora. These can be shown to have great potential interest in studies on how connectors are acquired by non-native speakers and the respective role of overuse, underuse, and misuse.

Content and Language Integrated Learning

DAVID MARSH AND MARÍA JESÚS FRIGOLS MARTÍN

Introduction

Content and language integrated learning (CLIL) is a dual-focused educational approach in which an additional language is used for the learning and teaching of both content and language. CLIL involves the use of language-supportive methodologies leading to authentic learning where attention is given to both the topic and the language of instruction. “Achieving this twofold aim calls for the development of a special approach to teaching, in that the nonlanguage subject is not taught *in* a foreign language but *with* and *through* a foreign language” (Eurydice, 2006, p. 8).

CLIL represents a holistic approach to learning which is heavily cognitive-based and which draws on an interplay of the theoretical foundations of constructivism and second language acquisition. In Europe it can be found at all levels of compulsory education. Most commonly found in secondary education, it has in recent years become a significant activity at primary level. There is little CLIL implementation reported in tertiary education.

Often carried out through interdisciplinary modules led by content and language teachers, or primary-level class teachers, the amount of time given to CLIL within the curriculum tends to remain low. Globally, the most common vehicular language is English, and in Europe there are increasing signs that CLIL is being adopted for the learning of other languages.

The Origins of CLIL

During the 1990s, the European Union was experiencing the triple pressures of integration, expansion, and modernization. Whilst multilingualism (the ability of citizens to speak different languages) acted as one of the pillars of European integration, education became a focal point for innovation, particularly as regards adjustment to the demands of the emerging information age.

Throughout this decade there was transnational recognition that a delivery gap existed between what was being provided in many countries as language learning and outcomes in terms of the ability of citizens to actively use these languages in their lives (see European Commission, 1995). There were language barriers identified (see European Commission, 1996) which were hindering the development of multilingualism and, consequently, undermining some of the goals of European integration.

Educational expertise in different disciplines, including additional language learning, became actively engaged in exploring different pathways by which to prepare young people for their future lives in information-rich environments. One example of this quest for pragmatic change was the 2007 formalization of a recommendation for all the European Union member states on “Key Competences for Lifelong Learning” (European Commission, 2007).

Following a four-year period of interdisciplinary and transnational expert dialogue, the term “content and language integrated learning” (CLIL) was adopted in 1994 and launched formally in 1996 (see Marsh, 2002). It designated a distinct range of methodologies that suited contexts where education was given in a language that was not generally the first language of the students involved. This included situations where students would be learning a foreign language, but also covered the learning of regional, minority, and heritage languages. The theoretical basis, and practical application, of CLIL was later recognized as applicable to contexts where students, often from migrant backgrounds, needed to accelerate their ability to learn through the majority language of the school (see Anderson, 2008, 2009).

In the early 1990s, initial support was given by the European Commission to expert organizations, initially in Finland (University of Jyväskylä) and the Netherlands (European Platform for Dutch Education) for a twofold purpose. First, to develop ways of articulating the principles of CLIL to the wider educational world, particularly in relation to language teaching and learning. Second, to develop a community of practice across the countries of the European Union, and beyond. This latter goal, which has actively attracted investment to the present day, is significant in enabling an understanding of how CLIL emerged and why it has continued to spread widely since the first two attempts to monitor and report on the situation were published (see Eurydice, 2006; Wolff, 2009).

During this period it was recognized that significant educational achievements in the simultaneous learning of language and content subjects had been made in different countries across the world. Examples could be found in relation to immersion (e.g., Canada and Catalonia), content-based language instruction (e.g., USA and Southeast Asian countries), bilingual education in European regions (e.g., Wales and the Valle d’Aosta region of Italy), and a range of highly context-specific educational environments such as border and international schools.

The use of differing terms to describe educational practices that had similar methodological approaches was found to be commonplace. The strategic development of CLIL in the 1990s involved searching for and identifying commonalities of good educational practice within and across different geographical and social contexts, and establishing bridgeheads by which these could be taken into mainstream education for the benefit of large cohorts of students.

The origins of CLIL were essentially organic and directly linked to the adaptation of educational life during the rapid emergence of the information age as it permeated home, school, and working life. Now, some twenty years later, the term is no longer viewed as a particularly European phenomenon and has spread globally.

The Emergence of CLIL

The emergence of CLIL in the 1990s can be linked to the language awareness movement which was developed in relation to both first and second language learning during the 1980s (Hawkins, 1984; Donmall, 1985).

Proponents of language awareness attempted to seek commonality of interest between those involved with first and second language teaching, and promote the curricular concept of “languages across the curriculum” (Barnes, Britton, & Rosen, 1969). Much of this early work was carried out in the United Kingdom on social inequalities and low standards of literacy in the first language (Davie, Butler, & Goldstein, 1972).

Language awareness is highly relevant in understanding why CLIL has continued to take root as in an age characterized by social, technological, and educational convergence.

One key feature of the new technologies which links to CLIL is that they involve social learning, are primed for the use of constructivist methodologies, and have become part of the connectivity lifestyle of young people.

The shift toward embedding features of language awareness into language-learning curricula was often hindered by time pressures. Language teachers can expect to achieve only modest outcomes with a broad cohort of learners if limited time is available within the curriculum. The early development of CLIL was characterized by the search for a complementary extra platform for developing language learning. "CLIL enables languages to be taught on a relatively intensive basis without claiming an excessive share of the school timetable" (Eurydice, 2006, p. 9).

This "extra space" enabled specific forms of methodology to be used to achieve goals not attainable within a time- and resource-restricted language-learning slot in a curriculum. The methodologies have developed into a form of education that surpasses "language learning," and which enables learners to experience integrated "language-acquisition-rich" learning environments. Use of these methodologies results in moving beyond linguistic goals that are predominantly utilitarian toward those that are essentially pragmatic.

CLIL is inspired by "important methodological principles established by research on foreign-language teaching, such as the need for learners to be exposed to a situation calling for genuine communication" (Eurydice, 2006, p. 9). And as noted by Wolff (2009, p. 560), "The experience (of CLIL) shows that both linguistic and content subject competence can be promoted within this integrated concept more effectively than when content and language are taught in isolation."

Now we briefly outline some of the major drivers that underpin the relevance and adoption of this educational approach.

Consolidation of Insights From the Educational Sciences

The theoretical basis of CLIL is not exclusive to any single domain. In Europe, it has often been the case that practice has preceded research, but such practice has been grounded in research insights that draw on diverse traditions and sources. CLIL is interdisciplinary, and as such it is not restricted to any single evidence base or theoretical tradition.

However, there are certain fields that directly apply to the language-learning aspects of CLIL practice. These are language awareness (LA), second language acquisition (SLA), psycholinguistics, and foreign-language learning (FLL). There are others, which relate to education in general, or subject-specific learning contexts, that apply to the design of CLIL methodologies. The most obvious of these are the philosophical underpinning and research traditions of learning theory (LT) such as constructivism and cognitivism.

As Wolff (2009) observes, CLIL "is at the interface of a number of academic disciplines which can result in controversies arising from differing perceptions, particularly in respect to terminology" (p. 563). The term "second language acquisition" is a classic example of a field that involves sometimes quite polarized orientation, and even diverse understanding of key terminology (see Doughty & Long, 2003). CLIL itself is prone to diverse forms of terminological misinterpretation, and this has further complicated the establishment of links between separate research traditions.

The relevance of insights from such different fields depends partly on the scale, scope, and type of CLIL model being implemented. These models differ widely (see Wolff, 2009), even if they utilize very similar core principles (see Marsh, 2002). The level of diversity often makes generalization and transfer of research insights problematic. This is particularly the case where specific forms of language development such as phonology are studied in situ without regard for other performance-based aspects of language competence.

The dual-focused learning objectives of CLIL mean that insight into its theoretical foundations need not only include but also go beyond domains mainly involved with language acquisition and learning. Consolidation of an understanding of CLIL also needs to reach out to modern cognitive theories. These assume that people learn by interacting with their environment, and that this process “which involves both the person’s previous knowledge and the environmental stimuli is seen as a constructive process. During this interactive process new knowledge is constructed and learned, and then integrated into the previous knowledge. The results of such knowledge constructions are always more than the sum of the environmental percepts; they are new concepts that cannot be foreseen. So learning is not adding information to information already stored, but constructing new knowledge.” (Marsh et al., 2009, p. 13). The co-construction of knowledge, of both content and language, is a key theoretical precept in understanding the educational benefits that are reported as surfacing through the implementation of CLIL (see Baetens Beardsmore, 2008). It is these benefits, often anecdotally reported at the outset, which have been one of the most significant driving forces for the uptake of CLIL.

Convergence of Insights From the Neurosciences

The field of neuroscience has developed as a separate discipline over the past thirty years. Since 2000, it has expanded due to ongoing advances in neuroimaging and other technology enabling researchers to look inside the brain to an unprecedented degree.

Research is increasingly examining whether knowing and using more than one language has a structural or otherwise positive impact on thinking and the brain (see Marsh et al., 2009). Dietrich comments that “advances in cognitive neuroscience in just the past two decades . . . have been breathtaking and they have brought unprecedented understanding and predictive power about how the mind works” (Dietrich, 2007, p. 27). The outcomes of studies conducted over the last forty years in largely nonlaboratory settings are dovetailing with recent findings often involving use of neuroimaging techniques conducted in laboratory settings. This is now enabling a breakthrough in understanding what happens within the mind and brain when a person learns or uses more than one language. This has important implications for education in general, and especially CLIL (see Bialystok & Petitto, 2010).

One of the significant findings is that changes in the brain’s electrical activity may occur much earlier than previously thought. Osterhout et al. report that “preliminary results from three studies indicate that classroom-based L2 instruction can result in changes in the brain’s electrical activity, in the location of this activity within the brain, and in the structure of the learners’ brains. These changes can occur during the earliest stages of L2 acquisition” (Osterhout et al., 2008, p. 510).

It has often been assumed that impact on the mind and brain would only be found if a person has a very high command of different languages. But studies such as Osterhout et al. (2008) suggest that changes in the brain may start even in the earlier stages of language learning. This has implications not only for recognizing the value of partial language competences, but also for understanding why certain approaches such as CLIL appear to lead to positive learning outcomes. The impact on the brain of knowing a second language, especially in relation to certain neural advantages, is increasingly being considered in relation to CLIL-type educational provision. Coggins, Kennedy, and Armstrong (2004) argue that it is “possible that bilingual learning can have a profound effect on brain structures” (p. 73).

The cognitive neurosciences stress the need for powerful learning environments. Yet for various reasons not enough language education is spent encouraging learners to engage

in higher-order thinking about meaningful content. There is now an intersection between the neurosciences and education, which acts as a driver in developing innovative approaches to learning such as CLIL. “After two decades of pioneering work in brain research, the education community has started to realize that understanding of the brain can help open new pathways to improve educational research, policies and practice” (OECD, 2007, p. 13).

Demand for English Language

Globalization has led to a demand for greater access to the English language (see Graddol, 2006). This has led to educational providers examining different ways of improving levels of English-language competence. One option considered involves the learning of nonlanguage content subjects through English. This has led to an expansion of schools and colleges that teach all or part of the curriculum through the medium of English. This shift toward teaching in English has raised discussion over what types of educational methodologies need to be applied if schools are to be successful.

Educational contexts differ with respect to the role of English outside the classroom and the types of exposure that learners have, which may be very high (e.g., Scandinavia) or low (e.g., Ethiopia). The adoption of “blueprint models” which may work in one country (e.g., immersion in Canada) is rarely desirable, and this has led to attention being given to what types of “language-supportive” methodologies might be both accessible and relevant in local contexts.

Demand for the Learning of Other Languages

CLIL-type educational provision is used for the teaching and learning of regional, minority, and heritage languages across the world. It is by no means restricted to English even if current indicators (in Europe only) show that English is the most commonly adopted vehicular language (Eurydice, 2006). It is an educational approach that is adopted to suit educational policies which aim to develop specific languages (e.g., within certain autonomous regions of Spain).

Internet-Based Networking

Internet-based networking is becoming an increasingly significant lifestyle phenomenon across many societies in the world, particularly amongst the younger generations. Countries obviously differ with respect to the use of multimedia technologies in education, but networking is an ongoing new development which has a bearing on education, including the learning of languages.

A study on the use of computers in European primary schools (Balanskat, 2009) shows that during 2008/9 some 75% of Europe’s primary teachers used computers in school, and all 30 countries reported investment in teachers’ digital competence development. The same report suggests higher figures for European secondary education. One feature of having access to computers and the Internet is the social capital to be gained when groups of students and individuals engage in networking.

Increasingly low technology costs and adoption of a common language enables CLIL to promote communication between schools and students through projects and exchange on an unprecedented scale. As networking becomes frequent in the lives of young people outside the school, there is pressure to introduce educational networking techniques for the purposes of curricular learning (see Rufer-Bach, 2009). In international linkage, access to a shared language is a key factor in enabling this to happen.

Competence-Based Education

Information-rich Internet-based societies require educational systems that develop specific types of competences. In Europe, amongst other regions, there is an ongoing shift toward competence-based education, which focuses on the ability to use knowledge, skills, and personal abilities in different contexts (see European Parliament, 2008). The constructivist basis of CLIL leads to learning outcomes that can be heavily competence-based in relation to both “knowing” and “doing.”

The Key Competences for Lifelong Learning in Europe Framework (European Commission, 2007) is one example of such an attempt to influence educational systems and the curricula. The recommended key competences for lifelong learning concern communication in the first and additional languages; mathematical, scientific, and technological competences; digital competences; learning skills; interpersonal, intercultural, and social competences; entrepreneurship; and cultural adaptability. Objectives of competence-based education such as these directly complement those of CLIL practice, particularly with respect to communication and learning skills.

Counterforces to CLIL

Issues that have been articulated against the implementation of CLIL have been mainly sociopolitical rather than educational. These have generally been linked to concerns about adoption of English as a medium of instruction, and an understanding that CLIL is a conduit for strengthening the spread of English language to the detriment of other linguistic or cultural interests (Marsh, 2002).

Protection of national languages (e.g., in Iceland, the Netherlands, Norway, Slovenia, Sweden), and nationalism (e.g., in Malaysia), have led to political discourse and actions which have hindered the development of this type of educational approach.

Another issue concerns cultural and linguistic diversity, often resulting from migration (e.g., in the USA), which has led to increased efforts to teach the national language to young people, and with a reluctance to allow additional languages to be used as a medium of instruction.

Finally, administrative (especially intraministry), international political agencies (e.g., those that seek to promote national interests), and professional bodies (e.g., the language teaching and learning industry) may seek to block the principles of curricular integration so as to protect vested interests and avoid influencing the status quo. As Mehisto suggests, “CLIL programme implementation often causes disjuncture—a tension between one’s current way of doing things and a new approach” (Mehisto, 2008, p. 109).

Research Insights on CLIL

Wolff (2009, p. 550) suggests that “CLIL is a practically oriented educational approach for which, until recently, researchers did not show much interest.” In Europe, CLIL practice has often preceded research.

But the increasing presence of CLIL-type provision in educational systems, both in Europe and in other parts of the world (e.g., Colombia, Malaysia, Singapore), as well as the interest of the European Commission to support CLIL implementation as a means to foster multilingualism (see European Commission, 2003), has led to a growing need to analyze its impact on learning processes, results, and contexts.

CLIL has recently emerged as a distinct area of interest for researchers who have previously depended on studies in second language acquisition (SLA), bilingualism, foreign-language learning (FLL) and applied psycholinguistics for achieving understanding.

Navés and Victori (2010, p. 25) observe that “just as with most of the CLIL programmes implemented so far—which tend to be of an experimental nature—most of the research done up to now may also be characterized as being exploratory.” To date, much of the available evidence has been anecdotal and generated by small-scale studies. There is common agreement among researchers (e.g., Lasagabaster, 2008; Wolff, 2009; Navés, 2009, among others) on the need for more empirical research on CLIL.

Existing evidence has been gathered across countries and regions, using different research methods and tools, on diverse aspects of CLIL implementation (see Seikkula-Leino, 2007; Lasagabaster, 2008; Navés, 2009; Ruiz de Zarobe & Jiménez Catalán, 2009; Wolff, 2009; Navés & Victori, 2010).

Research has generally been on language learning within CLIL. However, other aspects of CLIL such as acquisition of content subject competence, development of mother-tongue literacy skills, learner autonomy, affective learning factors (motivation and self-esteem), and cognitive development, are increasingly being reported.

Future Trends

Given the complexity of international educational comparisons and the ongoing unfolding expansion of interest in CLIL, it is only possible to provide some conjecture on the future of this educational approach.

There is an increased demand for English language in many countries, which may lead to greater adoption of this language as a medium of instruction (see Graddol, 2010). There is also greater understanding of the types of educational methodologies that need to be applied if schools are to successfully teach (partly or otherwise) through the medium of English as an additional language.

Global competition between universities and research institutes will involve increasing numbers of degree programs being taught through the medium of English language. This may lead to more secondary level schools opting to prepare students through partial teaching of academic subjects through the medium of English.

There is increased pressure for systemic structural change in certain educational systems to adapt to the social and technological changes in the wider environment (in Europe and elsewhere). This change involves moving educational practice away from “transmission models,” which have stubbornly remained commonplace, toward constructivist participatory modes of learning. CLIL may act as a catalyst for change in this respect (see Mehisto, 2008).

Focus on learning sciences and brain research will expand (due partly to the current trends seen in OECD countries, and particularly in respect to the OECD Programme for International Student Assessment—PISA) which may lead to national initiatives exploring the link between understanding of the brain and educational practice. This may focus on the significance of competence-based learning through constructivist methodologies within situated collaborative environments. These mirror good CLIL practice, and are likely to lead to recognition that CLIL provides good learning environments for both content learning and language development.

Finally, perhaps the most significant ongoing development concerns what is termed Learning 2.0. New technical solutions that emphasize social learning through networking are likely to become increasingly developed and accessible. Partnerships between technical

providers, publishers, and educational agencies are likely to generate opportunities for learning, both within and outside the classroom, which could complement existing forms of CLIL implementation.

Content-Based Instruction in English for Specific Purposes

DONNA M. BRINTON

The field of teaching English to speakers of other languages (TESOL) abounds with a veritable “alphabet soup” of acronyms: English language teaching (ELT), English-language learners (ELLs), English for general purposes (EGP), English for academic purposes (EAP), English for specific purposes (ESP), and content-based instruction (CBI), to name just a few. ESP is particularly rich in acronyms that describe its various subdisciplines: English for science and technology (EST), English for business and economics (EBE), English for legal purposes (ELP), English for medical purposes (EMP), English for occupational purposes (EOP), and so on.

Confusion and Boundary Disputes: EAP? CBI? ESP?

It is understandable that those who first enter the field of applied linguistics may feel lost in this alphabet soup. And those of us who teach courses in TESOL methodology spend a considerable amount of time explicating the meanings of acronyms such as English as a foreign language (EFL), English as a second language (ESL), English as an additional language (EAL), and the like. However, even more weathered veterans of the field may pause to ponder the differences between the closely related “cousins” ESP, EAP, and CBI and ask “Where are the boundaries?” As we will see in this entry, this confusion relates to the tendency of ESP and CBI to encroach upon each other’s territories. The confusion engendered as a result is made all the more marked by competing claims in the literature about where the boundaries between these two territories lie. To begin resolving the dispute, let’s first look at several instructional scenarios:

1. At Lakeridge Elementary School, teacher Tarry Lindquist uses social studies as a core of her fifth grade classroom, integrating aspects of science, reading, language arts, and art into the core curriculum. For example, at the beginning of the school year, students read legends and stories about First Americans (language arts), studied hunters and gatherers and the land bridge theory (social studies), learned about stewards of the earth (science), and made block prints and stencils with Northwest Indian designs (art) (Lindquist, 1995).
2. At UCLA, undergraduate students in a multi-skills ESL class taught by lecturer Linda Jensen studied a unit about the First Amendment of the US Constitution. In this unit, they viewed video footage of authentic university lectures from a communications studies course and read related excerpts from the course text as well as other related articles. Reading, writing, speaking, and listening activities centered on the topic of First Amendment rights (e.g., dress codes, speech codes on campus). All language and skills instruction used this context as a point of departure (Weigle & Jensen, 1997).
3. Based on a needs analysis of final year projects for engineering students at Hong Kong University of Science and Technology, lecturer Lynne Flowerdew targeted the development of students’ critical thinking skills. Identifying the genre of problem solution as

- critical to students' ability to complete this project, she obtained samples from the Engineering Department, analyzing the constituent elements of these final projects. Students in the ESL course were instructed to work in groups to identify a project focus; they then received instruction in the genre of the problem solution report. Drafts of these reports received instructor feedback. Students were also required to double-check the feasibility of their solutions with a subject specialist (Flowerdew, 2000).
4. In the intensive English program (IEP) of Indiana University, students in Joy Egbert's elective class "Kids and Computers" engaged in an exchange with second and third grade children at a local elementary school. For the first step in the exchange, the IEP students created computer-based slide shows about their culture. They then began a series of school visits, the aim of which was to teach the children computer skills and to collaboratively produce slide shows. To reflect on what they learned during the process, Egbert's students participated in electronic journal exchanges with the instructor (Egbert, 2000).
 5. At the Colchester English Study Centre, Joan Allwright conducted a short course for visiting medical professionals with the aim of improving their English for professional discourse purposes. To better analyze needs, participants were asked to complete a self-report questionnaire identifying areas of need in their communication skills. Participants were then asked to participate in case conference simulations (based on real medical cases). Following the simulations, the teacher shared actual clinical solutions to the cases and provided feedback on language (Allwright & Allwright, 1977).
 6. In Mrs. Macias's sheltered section of ninth grade English, there were 25 students from different countries. The sheltered course followed the regular English 9 syllabus but enrolled only non-native English speakers. In the course, students read well-known short stories in English and an abridged version of the novel *Great Expectations*. In the sheltered section, the teacher included additional vocabulary exercises and provided students with extra study questions. She also lectured more than in her regular English 9 class (Adamson, 1993).

At first glance, most would agree that scenarios 1, 2, 4, and 6 above represent examples of CBI in action, while scenarios 3 and 5 represent rather clear-cut examples of ESP. However, identifying instances of CBI or ESP and articulating the differences between them is quite another thing. In the section that follows, we will look at historical attempts to chart the boundaries of ESP and revisit the scenarios.

Mapping the Territory: ESP

Over the years, numerous attempts have been made to "map" the territory of ESP (Strevens, 1977; Hutchinson & Waters, 1987; Johns, 1991; Jordan, 1997; Johns & Price-Machado, 2001). Two of the most commonly referred to maps in the ESP literature are those proposed by Strevens and Hutchinson and Waters (see Figures 1 and 2).

Although differing in the boundaries they draw, these maps tend to exhibit some overlap regarding the following aspects of the territory that they chart as ESP. First, ESP is seen as distinct from EGP, which in the tree diagrams these experts draw is represented as a separate branch of ELT. Second, there tends to be a sharp division drawn between occupational or vocational ESP and the varieties of special purpose language instruction that occur within academic institutions. Finally, EAP is often singled out as distinct from its other more specific academic counterparts, such as EST.

Figure 3 Three prototype models of CBI as proposed by Brinton, Snow, and Wesche (1989)

Mapping the Territory: CBI

Early work on CBI (Brinton, Snow, & Wesche, 1989; see also Brinton, Snow, & Wesche, 2003) identified the following three prototype models of CBI (see Figure 3):

1. *Theme-based instruction.* Themes of specific interest, relevance, or both to the learner provide the organizing principle for the course. The theme of each unit serves to contextualize new language that is presented and provides the point of departure for skill- and language-based instruction and practice. Typically, a theme extends over several days or even weeks, providing rich linguistic input and creating the necessary conditions for learners to acquire new language.
2. *Sheltered instruction.* Students for whom the language of instruction is a second or additional language (L2) are separated or “sheltered” from their first language (L1) (i.e., mainstream) peers for the purpose of content area instruction. In most versions of this model, the content instructors who teach the sheltered section of the course receive specialized training in techniques to help students access the content material and to provide a nurturing atmosphere for the learning of both language and content. In theory, students’ exposure to the rich academic language and complex concepts presented in the sheltered class provides the necessary conditions for L2 acquisition to occur.
3. *Adjunct instruction.* One or more content area course is paired with a language course. At the outset of the course, as well as on an ongoing basis, the instructors negotiate their syllabuses to coordinate their instructional objectives. Typically, the objectives of the language course are identified with respect to students’ linguistic needs in the content course, though adjustments in the content course objectives may also occur. L2 acquisition occurs (a) through students’ exposure to the academically challenging language of the content course and (b) through the systematic linguistic guidance provided in the language course.

In proposing these three models, the authors caution that they are intended as prototypes only, and as such are meant to allow “consideration of other content-based variations which combine features of the three” (Brinton, Snow, & Wesche, 2003, p. 23). Ostensibly, these authors foresee innovations in CBI models as combining features of the existing prototypes but differing in some significant way—that is, arising out of the varied instructional settings in which the model is to be implemented and the specific needs of the students in that setting.

In the intervening years since the initial publication of *Content-Based Second Language Instruction* in 1989, numerous innovations in CBI models have arrived on the scene. These innovations have been well documented in the CBI literature. Figure 4 presents an updated map of CBI, as proposed by Brinton (2007). As represented in this diagram, the three original prototype models continue to flourish. However, they have continued to adapt to

Figure 4 An updated map of CBI's territory (© D. M. Brinton, 2007)

the settings in which they are used, causing the creation of several subbranches and even other new "hybrids."

Note that detailed information on the recent models depicted in Figure 4 are contained in the following sources: simulated adjunct (Brinton & Jensen, 2002); sustained content (Pally, 1997, 2000; Murphy & Stoller, 2001); and modified theme-based (Stoller, 2002).

Boundary Parameters: ESP and CBI

The early 1990s witnessed a great deal of discussion of both the common ground shared by ESP and CBI and their essential differences. Agreed-upon similarities include the following (Johns, 1992, 1997; Brinton, 1993):

1. ESP and CBI share a dissatisfaction with the traditional abstraction of language from its natural environment and real language use.
2. They share a concern that general purpose English courses cannot prepare students for the demanding linguistic, rhetorical, and contextual challenges of the real world.
3. They use genuine discourse from the real world to ensure that classroom content reflects the target situation.
4. They engage students in meaningful use of language rather than in activities that focus on the language itself.
5. They expand the definition of language teaching to include cognitive skills and critical thinking.
6. Finally, both ESP and CBI have as their goal the transfer of language skills and content to real life.

The differences of opinion regarding the territory covered by ESP and CBI, however, tend to loom larger. In an article originally published in 1992 and subsequently republished in 1997, Johns makes the following claims:

1. ESP has a rich research tradition, unlike CBI, its younger cousin.
2. It serves adult language learners internationally, while CBI is anchored in the English-speaking world and is linked to K-12 settings.
3. ESP courses often focus on one skill, while CBI courses favor an integrated, all-skills focus.

4. ESP is grounded in linguistically oriented and text-based research, while CBI research is concerned with the immediate classroom and issues of pedagogy (e.g., student affect, materials/curriculum design, and instructional strategies).

Disagreeing with these claims by Johns, Brinton (1993) responds as follows:

1. Both CBI and ESP are international in scope, as witness presentations on CBI programs from all over the globe at the international TESOL Conference.
2. Both CBI and ESP share a research base, as witness ongoing research in sheltered classrooms on the discourse of teachers and learners.
3. ESP grew out of commercial ventures, and even today often displays a commercial bent; CBI, on the other hand, grew out of academic needs and remains firmly entrenched in academic institutions.
4. ESP populations are brought together in the common pursuit of expanded language proficiency in a given domain and are thus identifiable; CBI populations are more varied, but are brought together through the vehicle of content.
5. Learners in ESP courses are instrumentally motivated since what they are learning is pragmatically informed (i.e., with immediate value to their profession or discipline); CBI learners are more intrinsically motivated, that is, by knowledge as an avenue to success in more general terms.
6. ESP is field-specific; CBI consists of a broad-based inquiry into academic knowledge, with a particular topic chosen not as an object, but as a vehicle of study.

CBI's Role in ESP: Putting a New Spin on the Debate

Though the above discussions are of some historical interest, they tend to focus almost exclusively on delineating the boundaries between CBI and ESP and do not lead to any satisfactory conclusion. In fact, as insinuated in the title of this entry, the more pertinent issue may lie instead in determining the place of CBI *in* ESP.

Eskey (1997) puts a new spin on the issue by eschewing the debate about boundaries and instead focusing on CBI's role as a course-organizing principle:

the content-based syllabus is best viewed as an even newer attempt to extend and develop our conception of what a syllabus for a second-language course should comprise, including a concern with language form and language function, as well as a crucial third dimension—the factual and conceptual content of such courses. (p. 135)

Having now established that CBI is a type of syllabus, we are in a better position to pinpoint its relation to ESP. Master (1997/8) concurs with Eskey, noting that CBI has the same status as the grammatical, notional/functional, situational, rhetorical, and task-based syllabi. Further, he argues, in terms of Wilkins's (1976) distinction between synthetic and analytic syllabi, CBI constitutes an analytic syllabus, since "significant linguistic forms can be isolated from the . . . context in which they occur [and] learning can be focussed on important aspects of the language structure" (p. 2). ESP, on the other hand, is simply one of two main divisions of ELT, the other being EGP (i.e., as previously pointed out by Hutchinson and Waters, 1987). According to Master, a CBI syllabus can be used in both EGP courses (in which case the theme-based model would pertain) and in ESP courses (in which case either the sheltered, adjunct, or other hybrid models would pertain). He concludes by noting that ESP is simply a domain of ELT that makes substantial use of the CBI syllabus.

Continuing the argument in much the same vein, Master and Brinton (1998) note:

In our view, CBI is a type of syllabus, the organizing principle on which a curriculum is based. It joins the other types of syllabi recognized in the field, namely, the grammatical, the notional-functional, the rhetorical and the task-based syllabus. The organizing principle is the content or subject matter on which any implementation of CBI . . . is based. ESP, on the other hand, is a division of ELT that has only one other member, namely, English for general purposes (EGP). ESP makes extensive use of the content-based and the task-based . . . syllabi. In other words, there is no “boundary” between ESP and CBI; instead, they operate independently because both ESP and EGP may make use of any of the syllabi. (pp. vii–viii)

Flowerdew and Peacock (2001) and Jordan (1997) examine the range of approaches that can be used in EAP syllabus design, tracing these by era. They note that while early EAP syllabi tended to be influenced by the lexicogrammar-based approach, syllabi in the 1970s were typically based on notional/functional or discourse-based approaches. Similarly, syllabi in the 1980s were frequently organized using either the skills-based or genre-based approach. These authors conclude their analysis by noting that a very influential approach to EAP syllabus design, especially in North America, is the content-based syllabus.

Finally, Basturkmen (2006) discusses the role of CBI in ESP courses, stating that ESP today makes extensive use of CBI. In passing, she notes several potential advantages of the CBI syllabus over alternative types of syllabi. These include the fact that CBI makes use of authentic texts embedded within the subject content, thus avoiding the pitfall of many other syllabus types, which remove or “export” the text from its natural context. Further, since CBI is an integrated, holistic approach, students are exposed to all skills and are required to synthesize from multiple sources.

Conclusions

To return to the scenarios presented earlier in this entry, we can now see that scenarios 3 and 5, both ESP courses, employ genre-based and discourse-based syllabi, respectively. The remaining scenarios (1, 2, 4, and 6) represent EAP courses that employ a CBI syllabus (i.e., a theme-based prototype in scenarios 1, 2, and 4 and the sheltered prototype in scenario 6).

This entry has examined the role of CBI in ESP. While early debates focused on delineating the boundaries between the two, later works more accurately analyze their symbiotic nature, stressing the role that a CBI syllabus plays in ESP course design. To conclude, CBI can not only be a highly effective way of delivering EGP courses but can serve as an equally efficient organizing principle for EAP and ESP courses (Brinton & Holten, 2001). Ultimately, an ESP course developer may choose to use a CBI syllabus as an organizing principle; she or he may also select another syllabus type (e.g., grammatical, notional/functional, genre-based, or task-based).

Content-Based Language Instruction

MARGUERITE ANN SNOW

Introduction

What is the “content” of second or foreign language teaching? A visitor to a second or foreign language class might observe the teacher teaching a grammar point such as relative clauses, students working in pairs to give directions from a map, or a small group listening to a taped folk tale. In a class at another school, the visitor might find the class reading an article about wildlife trafficking one day, and, in the next class session, participating in an activity in which they read biographies of wildlife traffickers, then state their opinions, using expressions such as “I think _____ should go to jail because _____.” At the end of the two-week unit, students prepare a poster and make presentations about endangered animals, displaying information on the causes of endangered status and current conservation efforts.

The “what” of language teaching has expanded in recent decades from an earlier focus on grammar in a structural syllabus, to functions such as making polite requests in a notional/functional syllabus, to students solving tasks in a task-based syllabus (Snow, 2001). In a content-based syllabus such as that used in the design of the wildlife trafficking unit, the content serves as the vehicle through which grammar, functions, skills, and tasks are presented and practiced by learners (Evans, 2006).

Content-based language instruction (CBLI) and its European counterpart, content and language integrated learning (CLIL), employ subject matter for second/foreign language teaching purposes. In other words, selected content is integrated with language teaching aims. The majority of work on CBLI approaches has originated in North America, while CLIL or “dual-focused” education is primarily a reaction to the need for plurilingual ability in schoolchildren as a consequence of the integration of the European Union, with particular focus on *all* youngsters “regardless of social and economic positioning” (Marsh, *n.d.*, p. 9).

The goal of CBLI and CLIL to create interesting, meaningful instruction that taps into learners’ interests and needs, in a variety of settings, with students of different age groups and educational levels, provides the common core of the two approaches. And, while CBLI and CLIL have developed from somewhat different traditions, the conceptual approach is fundamentally the same in their dedication to topics and subjects as the basis for materials and course development. Moreover, both have local and international reach. As such, the two are treated in this article as complementary labels for essentially the same overall instructional approach. The scope of this entry will focus primarily on CBLI, given the author’s expertise; the reader is encouraged to explore the network of web sites and platforms dealing with CLIL, including the refereed journal devoted to CLIL issues and projects (www.icrj.eu).

Three Main CBLI Models

CBLI is an umbrella term for a variety of models that differ in the degree of language and content integration. At one end of the continuum are “language-driven” models; at the

DOI: 10.1002/9781405198431.wbeal0192

other end are “content-driven” models (Met, 1998). In the early days of CBI, Brinton, Snow, and Wesche (1989) described three prototype models—theme-based, sheltered, and adjunct. These prototype models have served a useful role in discussions about how to structure CBLI programs in different instructional settings.

Theme-based courses, popular in both second and foreign language settings, consist of classes taught typically by the language teacher (not a content specialist). The theme is “exploited” for grammar, vocabulary, and functions; typically the goal is to integrate the teaching of listening, speaking, reading, and writing skills around the designated theme. In both English as a second language (ESL) and English as a foreign language (EFL) settings, the theme might be selected for student interest or need and teacher content specialization. In EFL, it may take into account the teachers’ comfort level with the model since a theme-based course may present challenges to teachers accustomed to a traditional grammar-based approach. A motivation for such courses in EFL is frequently to challenge students at the high intermediate or advanced proficiency levels.

The “Animals in the Language Classroom: Teaching English and Critical Thinking in a Social Issues Class” unit briefly described above is a theme-based unit developed by Heidi Evans for Japanese students at Kwansei Gakuin University. Her goals were to provide student with opportunities to increase their English skills and deepen their knowledge of a content area of interest. Her goal for improving her students’ English was to give them opportunities to further develop oral, written, research, and presentation skills through in-class tasks and out of class homework and practice. In terms of the content, Evans wanted her students to link previous knowledge and experiences to new information and raise students’ awareness of animal issues at local and global levels (Evans, 2006).

The immersion model in the elementary foreign language setting is perhaps the best known example of the second prototype, the *sheltered model*. In it, students receive a substantial amount of instruction in the second/foreign language, typically taught by a teacher primarily trained in the content areas. Pressure from English-speaking parents in the mid-1960s who wanted their children to acquire high levels of French as a second language led to the establishment of the first immersion program in the Montreal suburb of St. Lambert (Lambert & Tucker, 1972). In this program, students received all instruction from the first day of kindergarten in French. English was introduced in second grade and other subjects were introduced in English in later grades until about half the subjects were taught in French and half in English by the sixth grade. Four decades of research in Canada have consistently shown that English-speaking students immersed in French attain higher levels of French than any other school-based model of foreign language instruction, and that they achieve in their academic school subjects, including English, at the same or higher level than their counterparts instructed in English (Genesee, 1987).

The immersion model spread to the USA in 1972 with the establishment of the Spanish immersion program in Culver City, California (Campbell, 1984). Research on this program and others with target languages in French, German, and, more recently, in such less commonly taught languages such as Japanese, Chinese, and Arabic corroborates the findings of the Canadian French immersion programs. Currently, there are over 300 immersion programs in the USA offered in 18 foreign or heritage languages. The immersion model expanded in the 1980s into “two-way” or “bilingual immersion” by incorporating native speakers of the immersion language (Lindholm-Leary, 2001). The two-way model has also grown in popularity in the USA with over 350 current programs in 28 states and the District of Columbia (see the web site of the Center for Applied Linguistics for updated figures for both types of immersion programs at www.cal.org). Further, the immersion model has spread well beyond its original French immersion roots to immersion programs for aboriginal students in Canada, and to both “early” and “late” programs in international venues

such as Australia, China, Finland, Hong Kong, Hungary, Italy, and Spain (Fortune & Tedick, 2008).

The sheltered model has also been implemented widely in US elementary and secondary schools with large populations of English learners. The primary goal of sheltered instruction is to teach academic subject matter using special instructional strategies that assist in making the content comprehensible and focusing on the skills, academic language functions (e.g., asking for clarification, writing definitions, etc.), and vocabulary students' need to succeed in school (Snow, 2001).

The third prototype program is the *adjunct model*, also referred to as "bridge" or "linked" courses. In this type of CBLI, students are concurrently enrolled in a language course and a content course. This model has most commonly been employed in the postsecondary ESL setting. For example, in Project LEAP (learning English for academic purposes) at California State University, Los Angeles, students who needed additional assistance with their academic literacy skills were concurrently enrolled in linked courses such as *Humans and their Biological Environment* taught by a professor of Biology and a language course taught by an ESL specialist (Snow & Kamhi-Stein, 2002). Participating content and language faculty designed activities and assignments that integrated the content with the language needs of the students enrolled in the linked courses. Adjunct courses have also been implemented with EFL students who need to improve their English language proficiency in order to access course content in programs such as international business or international policy studies (Jourdenais & Springer, 2005).

"Discipline-based" programs have also been designed in the postsecondary foreign language setting where foreign language and content area faculty work together to link their courses. At the University of Minnesota, courses in the major European languages were linked with social sciences disciplines, and at Brown University, a course in *Japanese Culture and Society* was linked with a content-based component in Japanese (Krueger & Ryan, 1993).

Over time, CBLI has evolved into new configurations with features of the various prototype models reworked to suit the needs and resources of different settings, blurring the distinction between the models but revealing the dynamic process of curriculum design in CBLI (Snow, 2005). Brinton and Holten (2001), for instance, describe a "simulated" adjunct course at the University of California, Los Angeles in which videotapes of actual lectures by content faculty provided the content base for academic ESL classes. Further, Benesch (2001) argues for "critical" needs assessment and rights analysis as a way to use CBLI courses not only as a vehicle for developing academic literacy, but as a means to assist students to develop social awareness and acquire the language tools to seek social change.

Implementation Issues

Along with the reconfiguration of CBLI models and the diversification of its goals, there has been ongoing discussion of issues of implementation. Stoller and Grabe (1997) proposed the "Six T's Approach" for dealing with issues of selection and scope of content in CBI. In this framework, material developers and teachers design courses around a *theme, topics, texts, threads, tasks, and transitions* in an effort to improve coherence in theme-based courses. More recently, Pally (2000) introduced the term "sustained" content and Murphy and Stoller (2001) expanded on the notion as sustained-content language teaching (SCLT), an alternative to the tendency for some theme-based courses to jump from topic to topic where one day students might read about capital punishment, the next day about competitive bike riding. SCLT has two major components: (a) a focus on the exploration of a

single content area or carrier topic, and (b) a complementary focus on L2 learning and teaching. In the context of adjunct instruction, the most complex model logistically, others have focused on such challenges as student language proficiency (Iancu, 1997) and issues of power and authority when content and language teachers collaborate (Goldstein, Campbell, & Cummings, 1997).

In recent years, there has also been a concerted effort to enhance the language teaching opportunities of CBLI following Swain's (1988) admonition that "not all content teaching is necessarily good language teaching" (p. 68). Thus, practitioners and researchers such as Gibbons (2006) suggest that teachers create a "language inventory" of the academic language features that can be found in a unit of instruction. This language inventory can then be used to design language objectives and learning activities that focus explicitly on the language connected to content tasks, and to guide the development of assessments to determine whether students are learning language while developing content knowledge. Similarly, Carr, Sexton, and Lagunoff (2006) have identified the common discourse patterns (e.g., analyze, classify, hypothesize, etc.) that English-language learners need in order to deal successfully with science content; others have focused on strategies for raising secondary school teachers' awareness of the language challenges of history (Schlepppegrell & de Oliveira, 2006). Finally, in the context of French immersion, researchers have devoted considerable effort to highlighting language instruction through systematic interventions such as form-focused activities and corrective feedback (Lyster, 2007) and collaborative tasks that focus on linguistic accuracy such as reformulation and metatalk (Swain & Lapkin, 1998).

Conclusion

This entry provided a brief glimpse into the vast world of CBLI and the various approaches to integrating language and content in a variety of settings with learners of different age groups and educational goals. Despite the variations in models, all are predicated on the belief that learning a second or foreign language is more efficacious when subject matter has a central role in the course curriculum—when the "what" of language teaching is expanded to include interesting, motivating content.

Context in the Analysis of Discourse and Interaction

INGRID DE SAINT-GEORGES

Context is a central concept in the analysis of discourse and interaction in all the major research traditions in applied and sociolinguistics. Early linguistics did not display much sensitivity to it (Scollon, 1998, p. 80) and tended to study utterances in isolation and without reference to context. Today, however, there seems to be a general consensus around the idea that we understand utterances because they fit or make sense within particular situations. Studies of discourse and interaction include some orientation to context, if nothing else because “language is always produced by someone to someone else, at a particular time and place, with a purpose and so forth” (Blommaert, 2005, p. 39).

Beyond general agreement that “context should be taken into account” (Jones, 2004, p. 22), however, researchers often disagree about what should count as context, or how much context should be taken into account in the analysis. It could be argued that the way context is treated is in fact what usually sets apart and distinguishes different approaches and research traditions (Tracy, 1998). Conversation analysts, for example, often described as interested in identifying universal conversational rules, usually advocate limiting the study of context to those elements which are evoked in the sequential unfolding of the text or the interaction. Institutional context, social background, gender of the participants, and so on therefore should only be attended to by the analyst if they show up in the interaction and are made relevant to the ongoing exchange by the participants. For others, such as critical discourse analysts, for example, it is the connection between language and social processes that needs to be explicated, and this requires examining how text and interaction are woven into the fabric of sociopolitical action, social structures, context of cultures, and so forth (Halliday & Hasan, 1985; Fairclough, 1989). These different perspectives, with many others, have given rise to heated debates (Tracy, 1998) and have strongly contributed to giving the field its current shape.

Early Work

Historically, several outstanding researchers have pioneered discussions on context in the study of discourse and interaction. Malinowski (1947, p. 306) is usually credited with being the first scholar to introduce the notion of *context of situation* to examine the “conditions under which a language is spoken.” About the same time, in the 1950s, a group of experts around anthropologist Gregory Bateson at Palo Alto (California) began to analyze closely filmed interactions, which led to decisive insights about the organization of face-to-face interaction. Attention to gestures, intonation, facial expressions, and space came to be integrated into the study of exchanges and communication (Duranti & Goodwin, 1992; Scollon & Scollon, 2009).

In the 1970s, Gumperz and Hymes (1972) further proposed that, in order to understand culture, one needed to pay attention to the “speech events” and activities in which speakers were engaged. Meaning was to be found in the social interaction and not just in the grammatical competences of the speakers.

DOI: 10.1002/9781405198431.wbeal0194

In various branches of sociolinguistics, linguistic anthropology, but also of course linguistics, pragmatics, and philosophy, scholars have highlighted context, making salient the importance of looking at “immediate environment in which a text is actually functioning” (Halliday & Hassan, 1985, p. 46) and at the actions participants in this environment are performing with language. In the 1990s, Kendon (1992) introduced the oft-quoted idea that this environment functions as a kind of “(back)ground” against which the text (the “figure”) becomes interpreted. While the “figure” is usually clearly identifiable (it is the focal event to which the participants are attending), the background is much fuzzier but contributes nonetheless to the production and interpretation of meaning.

Exploring relations between figure and ground has raised numerous methodological questions for the study of interaction: What are the boundaries between context and the text that it is context to? How can researchers study what is “unattended” or ignored in a situation? How do they know what aspects of the attended context speakers orient to (Duranti & Goodwin, 1992, p. 4)? Three seminal publications in the early 1990s address these questions and others: “Some Context for Context Analysis: A View of the Origins of Structural Studies of Face-to-Face Interaction” (Kendon, 1990), *Rethinking Context: Language as an Interactive Phenomenon* (Duranti & Goodwin, 1992), and *The Contextualization of Language* (Auer & Di Luzio, 1992). These works were the catalyst of much subsequent work on context in discourse and interaction, and they highlight three key concerns. First, they show that in all research traditions “it is a recurring methodological problem to know at what level to define the situation one studies” (Scollon, 1998, p. 79). Second, they underline the fact that what gave rise to an increasingly complex and interactive understanding of context was the fertile interplay between a host of theoretical orientations (including, but not limited to, the ones presented here). Finally, they stress the particularly productive role played by discussions of context in the investigation of the relations between language structure, language use, social organization, and culture (Duranti & Goodwin, 1992, p. 32).

The Problem With Defining Context

The notion of context has been described by many as “notoriously hard to define” (Duranti & Goodwin, 1992, p. 2; Tracy, 1998). Not only does it mean different things in different research paradigms, but more generally the range of contexts in which utterances are considered can also vary widely. Researchers of context thus regularly stress that processes of different magnitude usually operate within a single interaction or event (Blommaert, 2005, p. 40). This makes it possible to study a range of phenomena as part of context, from the more microscopic (e.g., the “intonation contours” that will lead to interpret “oh” sometimes as an expression of surprise, sometimes as an expression of irony) to the more macroscopic phenomena (e.g., the social structures, such as the military, the global economy, the world system which, functioning as a sort of matrix, elicit, permit, or prevent certain kinds of communicative acts). From a practical viewpoint, Blommaert (2005, p. 40) notes that people seem to show remarkable ease in identifying what contextual cues are relevant for interpreting a situation or to convey the meaning which they want to convey (though sometimes they get it wrong). Blommaert thus proposes to define context minimally as “the totality of conditions under which discourse is being produced, circulated and interpreted” (2005, p. 251), and summarizes the question of context by saying that it “addresses the way in which linguistic forms—‘text’—become part of, get integrated in, or become constitutive of, larger activities in the social world (see also Scollon 2001)” (p. 39). Jones (2004, p. 25) prefers to talk about context (*Umwelt*) as “an individual’s environment of communicative possibilities.” Other authors choose more specific definitions of context. Van Dijk (2009) for example takes context to be the mental models and representations speakers use to make their contribution appropriate to the situation in which they find

themselves. He takes these mental models to be the mediating link between language and society. Schegloff (1987) prefers a talk-intrinsic definition of context, focusing on speech exchange systems as the context for interaction. Preceding or following utterances, the turn exchange system, or preferred responses become key sites to study even cultural aspects of interaction.

As Scollon (1998, p. 79) reminds us, metaphors of context will always put the spotlight on some aspects of the communicative process while diverting from others. For example, he argues, if we take context to be what “surrounds talk,” we might fail to pay attention to what is “in” the communication (the history of experience embodied in the speaker, the linguistic codes or genres she masters, the registers she has access to, etc.). If we focus on what is “in” the communication we might miss all those aspects that are not directly oriented to by the interactants in their discourse, but which might be nonetheless relevant to its production and interpretation.

Key Discussions

Several key discussions have shaped thinking about context. Early on, scholars often approached the problem of context by trying to identify what were ingredients of context, or parameters for it. A well-known example is Hymes’s (1972) SPEAKING grid. This acronym was devised as a mnemonic tool to help analysts remember to pay attention to several contextual parameters in the analysis of a speech event: the Setting, the Participants, the Ends and goals of the event, the sequence of Actions, the Key (i.e., the manner and tone of speech), the Instrumentalities (i.e., the channels of communication used), the social and cultural Norms foregrounded in the interaction, and the Genre (or text types) selected. By coming up with lists of this kind, Scollon (1998) notes, scholars were not interested simply in the “journalistic analysis of the five Ws—who, what, where, when, and why—but were concerned with the ways in which any communication must be interpreted against the context of these elements” (pp. 79–80).

Other researchers have conceived of context in terms of “layers.” Fetzer (2004), to name just one example (but see also Halliday & Hassan, 1985, p. 12; Fairclough, 1989, p. 25), distinguishes between “linguistic context” (genre, intonation, preceding utterances), “social context” (participants, roles, situations, physical and psychological dispositions), “socio-cultural context” (organizational dimensions, sociohistorically constituted institutions), and “cognitive context” (memory, prior knowledge, mental representations, etc.).

The metaphors of parameters or layers of context have, however, come under criticism. First, thinking in terms of “layers” risks hiding the many connections existing between different levels (Jones, 2004, p. 22). This has led scholars to specifically attempt to explain how, for example, the linguistic context (intonation, indexical meanings) relates to social and sociocultural contexts (roles, group culture or subculture). The seminal work of John Gumperz on contextualization cues (1992) crucially looks into such issues. Second, many earlier views tended to display context as something “already there” and “stable,” an “inert container” for actions. Scholarship in interactional sociolinguistics, for example, has shown on the contrary that context is something that speakers build and transform as they go along. This is possible because speakers in an interaction do not bring along the same “contextualization universe.” They might come with a different understanding of a situation, different goals and positions within it, have access to different resources and repertoires. This asymmetry might lead them to want to have a specific view of the situation acknowledged, recognized, or accepted (Blommaert, 2005, pp. 43–5), and they might very well attempt to challenge or change the definition of the situation. What this shows is that language is in fact both context-dependent and context-creating. It may serve to “frame”

a situation in a specific way (Goffman, 1974), and it can be used to signal changes in the roles and alignments interactants are taking up toward each other.

In the study of context in interaction and discourse, researchers have sometimes viewed context as the “mechanical frame” placed upon communication (the “container” view), others have seen it as the “conduit through which it occurs,” and still others, more recently, have become interested in the “socially constructed nature of these frames and contexts themselves” (Scollon, 1998, p. 83). The study of context has entailed looking at how the properties of discourse (syntactic, semantic, prosodic, argumentative, etc.) are constrained by the situation in which speech occurs, but also at how these properties become resources to organize the interaction (coordinate action, display identities, etc.). It has highlighted the necessity to consider how historical, cultural, or social frames influence the situated conduct and behavior of people but also how this situated conduct is sometimes used by them to evaluate, discuss, or challenge frames presented as already constituted (Filliettaz, 2006).

New Contexts of Scholarship and New Issues

Today, changes in the context of studying interaction and discourse are raising new issues, inviting scholars to investigate hitherto “forgotten contexts” (Blommaert, 2005, pp. 55–66). Social changes such as increased mobility of people and a more globalized economy suggest the need to “open up the circumference of analysis” (Scollon & Scollon, 2004) in several directions. Researchers are, for example, questioning views of language and context grounded in the Anglo-American or Western worldview (Makoni, 2005), and the kind of “ethnocentrism” it often entails. Blommaert (2005, p. 48) thus considers that many of the traditional assumptions about interaction (for example, that there are shared meanings and common ground among participants, or a symmetric contribution to the interaction) might well reflect Western context and bias. There is a great variety of sociolinguistic contexts that differ from this broad Western view. Mobility of speakers also makes particularly salient that a lot of what is going on in interaction is linked to other situations, traditions, and experiences that are in fact “recontextualized” in the situation. While interactions are always local, there are elements that transcend the moment in which they are produced (Blommaert, 2005, p. 45).

This recognition also suggests the need to probe not just the context of the researched, but also that of the researcher and the research process. Two kinds of questions can be asked here (Blommaert, 2005, pp. 59–65). The first one is: What is the context that the researcher takes for granted? For example, critical discourse analysis works from the assumption that many encounters are characterized by a power imbalance (e.g., doctors are more powerful than their patients because of status, knowledge, etc.) that is the unquestioned context for much of the research. This fails to acknowledge that there are cases of doctor–patient interaction which run otherwise. So the context of power imbalance itself could turn into an object of investigation. The second question has to do with what Blommaert terms “data history” (2005, pp. 64–6). Some research is very much time-bound. To carry out ethnographic research about Hong Kong’s handover to China (Scollon, 1997), for example, a specific set of economic, social, political, and personal circumstances needed to co-occur to make it possible to gather the specific data the researcher needed. This highlights the need to reflect on these circumstances and to make clear what is specific about them.

The development of new technologies of communication also challenges some of the assumptions that were made about context when sociolinguistics was overwhelmingly dominated by the study of face-to-face interaction. With face-to-face interaction, the focus was on situations of copresence and mutual monitoring. In computer-mediated

communication, notions of setting, participation, or attention shift. Jones (2004) shows that, in digital surroundings, attention is often polyfocal (there are several foci of attention between the physical world and the virtual world), and participation can be manipulated (conversational partners can be turned on and off the screen). Multiple figures are attended to against the backdrop of multiple grounds.

More widely, there are many linguists today challenging traditional orthodoxies about the nature of language (Scollon, 2001). They question the idea that there is such a thing as “a language,” conceived as “a priori ontological system” (Le Nevez, 2008). Rather than taking language to be a fixed mode, they view it as a repertoire of practices. Meaning and communication emerge from social interaction. This body of research pays less attention to text, and more to the ways in which texts “fit into the web of places, practices and communities that humans inhabit” (Jones, 2004, p. 31). For others, understanding communicative practices necessitates knowing more about the ways in which text interacts with other modes of meaning making (Jewitt, 2009). With these views of discourse, the traditional “figure” of language dissolves. It is no longer a repertoire of stable meanings, “there for use.” And with this shift comes the necessity of revisiting the traditional “background” of “context” with new tools and theories, and the need to question anew the idea of “text.”

In the 1990s, there was a clear move away from static conceptions of context, and toward more complex, dynamic, active, and interactive views of contextualization. This trend still continues. What sets apart discussions of context then and now is probably that “local talk-in-interaction” is no longer the sole unit of analysis and that new lines of inquiry are opening up.

We find several trends. One could be qualified as a “historical” trend. We now find researchers interested in tracing what happens to discourse not just in single speech events but across time and place. They develop a “polycontextual” view of discourse and interaction (Leander, 2002), and seek to understand not just the situation itself, but the chain of events that has led to an interaction or which emanates from it (Scollon & Scollon, 2004) and the relations between speech events. There is also an expansion in the range of phenomena that are taken into account. Scholars are going beyond previous studies of nonverbal communication to include not just gaze, gestures, and body movements but also the built environment, logos, graffiti, and so on to think about how spatial surrounding affects what it is possible to mean and say (Pennycook, 2007). They are also rethinking previous notions of “layers of context” by becoming interested in the issue of “time-scaling” of events (Scollon & Scollon, 2009). In interaction, processes belonging to different “timescales” come together. The reframing and negotiation of context are usually easier to carry out when dealing with processes on smaller timescales (for example, negotiating the role one will take up in a situation) than when dealing with large-scale societal structures (e.g., negotiating a school reform). Researchers thus become interested in studying the weight and impact of some contexts over others (Kell, 2009; Hult, 2010). Through these studies, scholars have often begun to question the usefulness of the very idea of context, proposing to replace it with other units of analysis.

Schegloff's words, “rethinking context is the omnipresent job of analysis” (1992, p. 215), are as relevant now as ever, whether in helping to make the breakthroughs that still await in the scholarship on context in discourse and interaction, or in helping to decide whether to abandon the notion of context altogether.

Conventional Methods for Assessing Vocabulary

JOHN READ

It is a time-consuming process to create new assessment procedures of any kind and to validate them adequately. Vocabulary assessments are no exception to this general observation, which means that there is a natural tendency for teachers and researchers to prefer established procedures rather than going to the trouble of devising new instruments. However, there are few vocabulary measures that can be considered standard tools, in the dual sense of being thoroughly researched and applicable in a wide variety of teaching or research contexts. Indeed, according to modern validation theory, validity is not an inherent property of an assessment procedure; rather, it is necessary to determine whether the procedure can be appropriately used for particular purposes and with specified populations of language learners. Thus, those who adopt a vocabulary test that they have not developed themselves have an obligation at least to conduct a trial with a sample group of the intended population of test takers to find out whether the test results can be meaningfully interpreted for their intended purpose.

The Word–Meaning Link

Traditionally, the essence of vocabulary testing has been to ascertain whether learners can make a link between words in the second language and their meanings. The meaning can be represented in three ways:

- a synonym or short definition in the target language;
- an equivalent word or phrase in the learners' first language; or
- a picture or some other graphic representation of the word.

The first two options are the basis for the most widely used types of vocabulary test item: multiple-choice and matching. The multiple-choice format has nearly a century of tradition behind it as the centerpiece of the psychometric approach to educational measurement in the USA and has been widely adopted in national examinations in other countries where large numbers of students need to be assessed with a high degree of reliability. Since multiple-choice tests of vocabulary work particularly well in psychometric terms, it is not surprising that vocabulary items were a key component of the Test of English as a Foreign Language (TOEFL) from its inception in the 1960s until the mid-1990s (Read, 2000, pp. 138–47). Eventually, the discrete vocabulary items were largely replaced by contextualized language use tasks, which were considered more valid measures of academic language proficiency for university admission purposes. Multiple-choice vocabulary items have been subjected to a variety of criticisms over the years, but nevertheless the format has been adopted in Nation's recent Vocabulary Size Test (Beglar, 2010), which is designed to give a reliable estimate of the total number of words known by first or second language users.

2 CONVENTIONAL METHODS FOR ASSESSING VOCABULARY

The matching format is best known from its use in Nation's earlier Vocabulary Levels Test (Nation, 1983; Schmitt, Schmitt, & Clapham, 2001), which was originally intended as a diagnostic tool for classroom teachers but came to be widely employed as a more general measure of higher frequency vocabulary in English. The format requires the learners to match each of a set of words with its definition from a selection given, or vice versa. This type of test is somewhat easier to create than a multiple-choice one, but it can be criticized for testing the target words in isolation, whereas standard practice in current multiple-choice vocabulary items is to present the word in a short (usually nondefining) sentence context.

The third option, pictorial presentation of the meaning, is particularly suitable for young learners or for older people who are not literate in the target language. The Cambridge English for Speakers of Other Languages (ESOL) Young Learners English tests (<http://www.cambridgeesol.org/exams/young-learners/yle.html>) make extensive use of pictorial material, particularly at the Starters and Movers levels, where the exam papers include items requiring the learners to match words and pictures. Perhaps the best-known standardized instrument of this kind is the Peabody Picture Vocabulary Test (Dunn & Dunn, 2007), which was designed primarily to diagnose learning needs of students in the American education system, but it could also be used with appropriate trialing to assess the vocabulary knowledge of second language learners across a wider age range. The test material, which is individually administered, consists of sets of four pictures. For each set the administrator says a word and the response task is simply to point to the picture which represents the meaning of that word. It should also be pointed out that this is one of very few examples of a test which assesses oral vocabulary; almost all other conventional vocabulary measures focus on words in their written form.

Other Aspects of Word Knowledge

The tests discussed thus far are limited in at least two ways:

1. They require the learners simply to *recognize* the correct response from the options given. This is often referred to as passive vocabulary knowledge.
2. They focus exclusively on the form–meaning link rather than other aspects of word knowledge.

Let us look at each of these points in turn.

Learners need to be able to *recall* the forms and meanings of words, as well as recognizing them. One test that systematically assesses recognition and recall of form and meaning both monolingually and bilingually is the Computer Adaptive Test of Size and Strength (CATSS) developed by Laufer and Goldstein (2004; available online at <http://hcc.haifa.ac.il/~blaufer>). The other common format for assessing recall of word forms is gap-filling, in which the target word is deleted from a sentence or a larger text and replaced by a blank. Gap-filling has traditionally not been favored in large-scale exams because there are often several words that can fill a particular blank, which means that the items cannot be machine-scored and there may be subjective judgment involved in determining which responses are acceptable. One gap-filling test that has been quite widely used for research purposes is Laufer and Nation's (1999) productive version of the Vocabulary Levels Test, in which some of the initial letters of each target word are given to ensure that there is only one correct answer. However, this makes a hybrid kind of test that only partially assesses recall of the words.

With regard to the second limitation of word–meaning recognition tests, a number of authors have pointed out that knowing a word has multiple components, including

knowledge of pronunciation, spelling, frequency, associations with other words, grammatical functions, and usage. Nation's (2001) analysis of what it means to know a word has been influential, as has his discussion of how the various knowledge components can be assessed. This broader perspective is often called "depth of vocabulary knowledge,"

There is really no standard method of assessing depth of word knowledge. One possible candidate is the word associates format (Read, 2000, pp. 180–6), in which test takers select several words that are associated with a given target word. In a recent review, Read (2012) notes that experimental versions of the format have been investigated by researchers in a number of countries, but it has apparently not been adopted as an operational test outside of the research context, and it really represents just one other component of Nation's vocabulary knowledge framework, beyond the link between word and meaning.

A second assessment tool that has created interest as a depth measure is Wesche and Paribakht's (1996) Vocabulary Knowledge Scale (VKS). Originally developed for use in a vocabulary acquisition study, the VKS first requires learners to rate how well they know the meaning of each target word and then to supply evidence of their knowledge in the form of a synonym or a translation, as well as composing a sentence containing the word. Thus, it is a kind of combination of self-assessment with conventional test tasks. Modified versions of the VKS have been used by a number of other researchers, but some critics (e.g. Bruton, 2009) have raised issues such as the conceptual basis of the instrument, whether it really forms a measurement scale, and its inability to deal with multiple meanings of words.

Vocabulary in Use

Moving beyond knowledge of words, we are also interested in the ability of learners to apply their vocabulary productively in speaking and writing tasks. This goes much further than the very controlled form of production assessed by the Productive Levels Test referred to above. It also means that the test designer cannot specify in advance which words will be elicited by the task; rather, it is necessary to evaluate in a more global way the learners' use of vocabulary in completing the task. There are essentially two approaches to assessing vocabulary use: by means of rating scales; and by calculating lexical statistics.

Rating scales constitute the conventional method of assessing spoken and written production in operational tests. This kind of scale defines a number of levels of performance, and for each level there is a descriptive statement of the typical linguistic or communicative features associated with that level. Normally, vocabulary use is just one of the criteria that raters are asked to consider. For example, let us take the Occupational English Test, which assesses the language proficiency of overseas-qualified health professionals wishing to practice in Australia (www.occupationalenglishtest.org). In the Writing subtest, which for doctors involves composing a referral letter based on case notes, one of the rating criteria is Appropriateness of Language, "including the appropriate use of vocabulary and tone in the response." Obviously, this requires a holistic and subjective judgment which does not target any particular words in the text. Raters need to focus on the overall communicative effect of each candidate's lexical choices.

The second approach, applying statistics, has quite a long history among scholars interested in analyzing the lexical characteristics of different types of written text. Two key concepts here are lexical variation and lexical sophistication. Variation (or diversity) refers to the extent to which the writer uses a wide range of words rather than just a restricted vocabulary. The traditional measure is the type-token ratio (TTR), which is a simple calculation of the number of different words in a text (types) as a proportion of the total number of words (tokens). However, a more reliable statistic is Malvern and Richards's D (Malvern, Richards, Chipere, & Durán, 2004), which is designed to deal with

4 CONVENTIONAL METHODS FOR ASSESSING VOCABULARY

a well-known weakness of the TTR: its being influenced by the length of the text. On the other hand, lexical sophistication is concerned with the proportion of lower-frequency words in the text. One influential measure of sophistication is Laufer and Nation's (1995) Lexical Frequency Profile, which calculates the relative percentages of words in four categories, essentially distinguishing between very high-frequency words and others. Meara and Bell (2001) have proposed as an alternative a measure called P_Lex, which controls for the fact that learner texts are typically quite short.

A recent development in large-scale proficiency testing is automated scoring of speaking and writing tasks (Xi, 2010). With this approach, a computer program is trained to identify linguistic features of texts which are associated with the judgments that human raters have made about the quality of the spoken or written performance, and lexical measures figure prominently in this process, at least for writing (Enright & Quinlan, 2010). In the current writing subtest of the internet-based Test of English as a Foreign Language (TOEFL) (iBT), each script is assessed both by a human rater and by an automated system. It remains to be seen to what extent automated scoring will supplant human ratings, but this represents an important new application of vocabulary measures in language assessment.

Thus, in conclusion, although there are a number of vocabulary measures that are widely known and used, they tend to have limitations of various kinds, including partial evidence at best of their reliability and validity. Several innovative procedures have been designed and investigated for research purposes, but few have been adopted for the assessment of learners in operational tests, which still rely mostly on established formats such as multiple-choice, matching, gap-filling, translation, and rating scales. It is important to clarify the purpose of the assessment and the nature of the vocabulary knowledge to be measured. As noted above, the terms "receptive" and "productive" can be particularly problematic. Although vocabulary research is a vibrant area of academic study, the value of its findings is significantly dependent on the quality of its measuring instruments and how appropriate they are for their intended purpose.

Conversation Analysis and Affiliation and Alignment

JAKOB STEENSIG

Introduction

When people respond in interaction they will invariably indicate whether they cooperate with aspects of the utterances they respond to. The concepts of *alignment* and *affiliation* are both used about cooperative responses, and, conversely, *disalignment* and *disaffiliation* are used about uncooperative ones.

The two terms “affiliation” and “alignment” have been in use about different types of responses for a long time; Jefferson (2002) distinguishes, for instance, between “acknowledgement” on the one hand and “affiliation” on the other. However, it is only recently that this difference was made explicit and explicated, and it was suggested that studying both processes could give analytical insight. This is also the point of view taken in the present entry. It will begin by introducing the distinction between the two concepts and then look at examples of how the concepts and the distinction between them can be used analytically.

Distinguishing Affiliation and Alignment

Stivers (2008) is the first to explicitly define and delimit the two concepts. This is done for the specific environment of responding to storytelling (see below). Stivers, Mondada, and Steensig (2011) attempt to generalize the distinction across activities. They conceptualize *alignment* as the “structural level of cooperation” (2011, p. 20) and see aligning responses as ones that “cooperate by facilitating the proposed activity or sequence; accepting the presuppositions and terms of the proposed action or activity; and matching the formal design preference of the turn” (2011, p. 21). This involves accepting the interactional roles involved in the activity; for instance, in the context of storytelling, accepting the role as a storytelling recipient (Stivers, 2008). *Affiliation* is, in this proposal, “the affective level of cooperation,” in that “affiliative responses are maximally pro-social when they match the prior speaker’s evaluative stance, display empathy and/or cooperate with the preference of the prior action.” (Stivers et al., 2011, p. 21). Table 1 gives an overview of key concepts in this distinction.

Table 1 Overview of alignment and affiliation features

<i>Alignment: structural level</i>	<i>Affiliation: affective level</i>
Facilitate and support activity or sequence	Display empathy
Take proposed interactional roles	Match, support, and endorse stance
Accept presuppositions and terms	Cooperate with action preference
Match formal design preference	

The term “affective level” is a rather vague and nonanalytic concept. It may capture the display of empathy and support of stance, but cooperation with action preference is not necessarily, in any obvious way, an affective issue. I have kept it, for lack of a better word, because this is the cover term that has been used in earlier discussions.

Below, we will try to clarify how the concepts of alignment and affiliation can contribute to understanding structural and “affective” issues of social interaction. But first, we will consider how the conditions for aligning and affiliating are set up.

Creating an Environment for Alignment and Affiliation

In order for a speaker to align or affiliate, there must be something to align or affiliate with. Excerpt (1) illustrates this:

(1) [Stivers (2008, p. 41), excerpt 6]

01 KAT: .tlk alright so Curts' parents come for dinner?,
 02 (.)
 03 LIA: #h[m#
 04 TAR: → [(m)m hm,
 05 (0.3)
 06 KAT: an' uhm_ (0.8) we're like
 07 LIA: h(h)m!/(0.8)
 08 KAT: “leave your ^dog;” “we'll babysit your dog,”
 09 (.)
 10 TAR: ((*gaze shifts to Katie*))
 11 KAT: [“we have uh dog £t^oo.”,]
 12 TAR: ⇒ [((*nodding*))]
 13 KAT: an so:_ his parents leave thuh dog,

Katie begins in line 1 to tell a story and Taryn responds to this in line 4 and line 12. In both cases, Taryn *aligns*, that is, she accepts the role as a story recipient, which contributes to maintaining the activity of storytelling, but only the nodding in line 12 *affiliates*. In line 1, Katie announces a story, that is, an activity that the recipient can align with, but there is no indication of stance and, hence, nothing to affiliate with. Line 8, however, is reported speech, revealing something about the teller's stance: It “portrays the offering as something they did with enthusiasm (note the pitch peak and emphasis on ‘dog’ and the quick succession of offers in line 8)” (Stivers, 2008, p. 42). Those features make it possible for Taryn to affiliate, that is, support Katie's stance or perspective, which is what she does by nodding in line 12.

Excerpt (1) also shows that alignment is relevant after virtually every interactional contribution. Everything that people say is part of some activity and has a format that next speakers need to deal with. Affiliation, on the other hand, is relevant only after utterances that take a stance or have specific action preferences.

Aligning and Affiliating are Interpretive Processes

Sometimes the activity with which the recipient can align is not as straightforward as in excerpt (1). In excerpt (2), Cora has told that she has the flu and is getting into what Jefferson and Lee (1992/1981) call a “candidate Troubles-Telling sequence”:

(2) [Jefferson & Lee (1992, pp. 527–8), excerpt 3, abbreviated, line numbers added]

01 LIL: → e- You sure sound aw_ful. [(hoarse.)]
 02 COR: [·t Oh:_ my God] I been

- 03 ·hhh running the highest temperatures you ever sa:w.
 04 LIL: → Oh m go:sh well let me hang up and let you get back to bed=

Jefferson and Lee argue that Cora's lines 2–3 are the beginning of a troubles-telling, but Lily's response in line 4 treats it as raising a problem with continuing the conversation and hurries to remedy that problem by suggesting that she close the call. Lily "may be properly aligned as the proposer of an inauspicious plan, and an intruder upon someone's 'trouble', but certainly not as a 'troubles-recipient'" (1992, p. 528).

Troubles-telling is, according to Jefferson (1988) and Jefferson and Lee (1992), a recognizable activity with the corresponding roles of a "troubles-teller" and a "troubles-recipient." It is, however, also an activity that is built up gradually, making it possible for the recipient to take other roles than that of a "troubles-recipient." It is a general feature of interaction that people can initiate activities in recognizable ways, but that recipients can still choose to interpret the activity as something else. Therefore, the work of an analyst (as well as that of a conversationalist) is to analyze how a contribution creates conditions for aligning, as well as how those conditions are interpreted and treated by the next contribution. Lily's response in line 4 can also be seen as an attempt to affiliate, displaying empathy with the stance that talking now is too much for Cora, but it may be missing the point if Cora is going for an empathic response to her troubles-telling. Therefore, the same is true for affiliation as for alignment: A recipient may affiliate with something that does not match recognizable attempts at creating an affiliation environment in the prior utterance.

Disaligning and Disaffiliating

Sometimes people respond in clearly disaligning ways. In excerpt (3), Frank has called to talk to Marge's husband, who is not present:

(3) [Jefferson & Lee (1992, pp. 524–5), excerpt 1, abbreviated, line numbers added]

- 01 MAR: I: would like to tell you that one of your: ·h uh brother
 (...)
 02 MAR: introduced my husband to a lady
 ((story about husband not coming home and spending
 his time with this lady, then coming home and just going
 to bed))
 03 MAR: ·hh well you know I was questioning about what was
 04 go[i n g o i n?]
 05 FRA: → [Well do you h]appen to have his phone number?

Jefferson and Lee analyze Marge's story as a "troubles-telling," making it relevant for Frank to be a "troubles-recipient." They see line 5 as Frank clearly disaligning by initiating a different activity and not doing any of the actions that a troubles-recipient could do. It is clearly also insensitive to the stance Marge is taking and to her call for empathy, and it is, thus, also a disaffiliative response.

Affiliating Without Aligning

People can disalign while still affiliating with their coparticipants. This is the case, for instance, when a speaker agrees with another speaker while, simultaneously, asserting more rights over the knowledge of what is being assessed. In excerpt (4), Gay has been reading a German phone number to Jeremy, who now assesses its length:

(4) [Heritage & Raymond (2005, p. 27), excerpt 21, abbreviated, line numbers changed]

01 JER: °Gosh°it goe:s (.) goes on'n on

02 GAY: Oh it doe:s Germany doe:s.

Gay's response is affiliative; it supports and agrees with Jeremy's stance in line 1. In some senses, it is also aligning: It accepts the activity (assessing) and furthers the sequence. But Jeremy's first assessment contains knowledge presuppositions that Gay's response does not align with. It suggests that the length of German phone numbers is something new and remarkable, and that this could be so to the recipient as well. But Gay's response is "*oh*-prefaced" (Heritage, 2002), marking that this is something that she already knew, and it contains a partial repeat (*it does*), that further emphasizes Gay's prior and independent access (Stivers, 2005).

Similarly, answers to questions can confirm and affiliate while, at the same time, taking issue with the knowledge or other presuppositions in the question. This can be the case with, for instance, answers that mark the question as inapposite (Heritage, 1998; Heinemann, 2009), "unaskable" (Stivers, 2011), or asked on the wrong grounds (Stivers & Hayashi, 2010).

Aligning without Affiliating

It is possible to disaffiliate in an aligning way. One example of this is when "noncommittal" responses occur at points where more engaged responses would be the affiliative thing to do. This has repeatedly been shown to happen in counseling and medical encounters. Excerpt (5) is a classic instance, from a call to a suicide prevention center, originally recorded and transcribed by Harvey Sacks:

(5) [Jefferson (2002, p. 1352), excerpt 11, abbreviated, original transcript conventions retained, line numbers added]

01 PAT: I cant go through with it I cant go through with the

02 evening I cant (sniffle)

03 DOC: uh huh

04 PAT: you talk I don't want to talk

05 DOC: uh huh

06 PAT: ((*laugh sob*)) it sounds like a real professional uh huh

07 uh huh uh huh (sniffle)

The patient is clearly going for something more than *uh huh* from the doctor, as indicated explicitly in line 6. The doctor's responses are disaffiliative in that they do not show empathy, and thus also decline to follow up on at least one aspect of the action preference (that the display of trouble get recognized in some way), but the doctor still aligns as a recipient to the patient's telling and its formal properties.

Stivers et al. (2011, p. 27) claim that disagreements with assessments also can be aligning (but disaffiliating) when they accept the activity (of assessing) and the knowledge division between parties that the first assessor has proposed.

Discussion

Any analysis of alignment and affiliation should be specific about how preceding actions create something to align and (possibly) affiliate with and about how responding utterances (dis)align or (dis)affiliate. But pointing out what is alignment and affiliation cannot

be an aim in itself. The concepts have analytical relevance only if they contribute to understanding how social cooperation (or the opposite) is done. Future work will show whether the concepts prove fertile for analyses, or whether it is better to use the sub-concepts listed in Table 1 above.

Conversation Analysis and Child Language Acquisition

MICHAEL A. FORRESTER

There is now an emerging body of work that can be best described as child-focused conversation analysis (child-CA). The main theme of the research centers on what is involved with children learning how to talk, with additional work on CA studies of childhood. An examination of the literature reveals the diverse themes and issues underscoring contemporary work found across many disciplines. This diversity reflects the fact that ethnomethodologically informed research in child-CA is not focused on language acquisition per se, but instead on how children learn to participate in meaningful social interaction, including language as a social practice. While all such work employs CA methods, the research questions, and underlying theoretical leanings, are diverse. Furthermore, the research designs are similarly varied, including single-case studies, longitudinal designs, cross-sectional comparisons, field studies, ethnographic descriptions, and participant observation. Whatever the design, approach, or data selection criteria employed, there is a shared commitment to the analysis of children's naturally occurring interaction in situ.

As a guide to the emerging literature, child-CA research can be classified into five general areas: (a) prelinguistic communication, (b) repair, (c) competencies and understandings, (d) grammar, and (e) childhood. Such a differentiation is to some extent arbitrary as many themes overlap, but employed here to give a sense of the emerging literature. While there may be some correspondence between subthemes and disciplines (childhood: sociology; prelinguistic communication: developmental psychology), child-CA research can be found in many areas. Furthermore, although there may be an implicit transdisciplinary orientation to describing and explaining the *development* of children's skills and abilities, this is not necessarily a shared aspect of child-CA work.

Prelinguistic Communication

Child-CA research in this theme has highlighted the earliest indications of young children's methodic social communicative skills. In a series of studies of preschool children age 1 to 3 years Kidwell (2009) demonstrates their emerging orientation to a normative social order and their gradual recognition that what is just as important as misconduct is whether your actions are detectable or not by caregivers. Highlighting instances where children make use of another child's gaze shift as a resource for shaping their own actions, Kidwell's (2009) detailed analysis of embodied action and sequence in talk-interaction, particularly gaze and "looking," speaks to a large domain of psychological research on joint attention, considered a cornerstone of language development. Similarly, Kidwell and Zimmerman (2007), in their examination of how very young children present objects to others, show that various practices are involved in making something observable and such "observability" of objects is often what inaugurates a sequence of interaction with another. The theme of what makes action observable is also considered in work by Lerner and Zimmerman (2003), who show how children employ the appearance of one action to accomplish another, and Kidwell's recent work highlights the significance of joint attention and orientation to

sequence for epistemic accountability (Kidwell, 2011). These studies, although not directly concerned with language per se, highlight the significance of behaviors underpinning the emergence of language.

Repair

How, why and under what circumstances children *repair* their own or others' talk represents a second theme. Through examining children's repair practices we can gain insight into how they understand conversation, and specific elements of the language system. As part of an influential corpus of child-CA work Wootton (1994) has documented the emergence of third turn repair. Initially re-requesting and outright rejections (say of the offer of an object) were mixed together, followed by a period where brief gestures were employed alongside a re-request, and by 18 months, acts of rejection were clearly differentiated from re-requesting. This careful analysis of one child's request and repair practices serves as an early example of how fine-grained analysis can reveal aspects of a child's competence hitherto unknown. The ability of a child to call on resources of self-repair and correction is also highlighted by Filipi (2007) in her examination of how one child responds to somewhat disinterested continuers in talk. More recently Forrester (2008) has documented the emergence of self- and other-initiated repair between the ages of 1 and 3 years, highlighting the fact that spontaneous self-repair is more common initially than (adult) other-initiated repair. Crosslinguistic comparisons, however, warrant caution given Laakso's (2010) work with Finnish children age 1 to 5 years, indicating that other-correction of children's speech diminished rapidly after age 2 years. Further, when children first use self-repairs, the lexical repair initiators typical of Finnish are not employed; and by 4 years, children are skillful in repairing their utterances for social interactive purposes, using adult-equivalent linguistic devices.

Competencies and Understandings

Attaining full membership of a culture entails children learning how to recognize and produce talk, *and* simultaneously display their understanding of talk as a reflexive social activity. They need to display to others their understanding of "talk" as an accountable set of social practices. Wootton (1997) talks of the acculturation of the child through emerging intersubjective understandings that are locally derived, that is, pertaining to very recent cultural and moral events.

In charting key aspects of the child's conversational skills and understandings Wootton (1997) comments that intersubjective "understandings" have three important properties: They are local, public, and moral. For example, these understandings are public in that the child's conduct is systematically sensitive to agreements and preferences which have been *overtly* established within earlier talk. Detailing and examining intersubjective understandings is central to the work of Tarplee (2010), who addresses the inherent difficulties of using concepts such as "feedback" to explain language development. Looking at displays of understanding, on a turn-by-turn basis, Tarplee (2010) highlights the child's orientation to sequential implicativeness, and makes the point that the particular kind of parent-child interaction where linguistic pedagogy is relevant is constituted by the structure of the talk itself.

A related child-CA study concerned with children's competencies questioned the assumed relationship between cognitive development and play. Examining 4–9-year-olds playing

together, Whalen (1995) demonstrated the detailed ways that children first initiate, then systematically organize and accomplish, fantasy play as a socially shared, thoroughly collaborative activity. Similarly, Sidnell (2011) analyses the talk of 3–4-year-olds during make-believe play. Focusing on how “what it is to know” is practiced by children, he details the manner in which epistemic rights about make-believe characters and events flow from participation in the activities, where children orient to knowledge as a structural domain imbued with significant moral importance.

In contrast, Church (2009) describes how children recognize and display disagreement and confrontation with adults and peers. In arguments, threats, and responses to potential conflict, young children use atypical dispreferred turn-shapes, highlighting their developing understanding of the “projectable” and conditional nature of turn taking. Church’s (2009) analysis indicates the subtle processes involved in children gradually learning how to produce accounts in their talk that dispel or displace potential conflict.

The potential difficulties children face when dealing with adults is brought out in the work of Wootton (2005). Detailing the manner in which children make requests, he considers whether there is any orderly connection between the grammatical form requests take and the sequences in which they happen. Over and above demonstrating the relationship between the child’s request form selection and patterns of “accountable alignment” particular to the preceding talk and action, Wootton (2005) draws our attention to the fact that transitions need to be understood with reference to the dynamics of the interactions the child is experiencing rather than relying on cognitive developmental explanations.

Grammar

Another theme of child-CA work subsumes topics such as language form, syntax, prosody, and conversation monitoring. Tykkyläinen and Laakso (2010) consider how 5-year-old Finnish children employ the “agreement-pursuing” question particle, showing that use is closely embedded with attempts at negotiating social relationships with peers, particularly during fantasy play. The role of adult input and how children begin to recognize the significance of turn taking is brought out in the work of Wells and Corrin (2004). Using an International Phonetic Alphabet (IPA) supplemented CA orthography they highlight how a child can recognize significant prosodic features, when and where to employ them, and what the results might be. Such work draws our attention to the subtle nature of prosody in turn taking and turn completion, where, for example, it is use of mid-pitch which projects the non-completion of a child’s turn—a nonfinal element which adults orient to.

Other structural features of the local management system seem unique to adult–child talk. Tarplee (1996), for example, has documented the phonetic repair work children produce in contexts where adults disguise direct correction by carefully designed temporal placing of turns-at-talk. Contrastingly, adults often produce repair initiators in their talk with children without explicitly locating what the trouble-source of the child’s prior turn might be. Corrin’s (2010) analyses of the talk of a 19–21-month-old indicates that self-repair can be initiated through potentially ambiguous adult turns in the ongoing sequence of talk.

Again, as with repair studies, crosslinguistic comparisons are emerging within child-CA work. Salonen and Laakso (2009) note that 4-year-old Finnish-speaking children produce fewer morphological and more syntactic self-repairs. They are also able to produce long and complex revisions of ongoing speech, and can monitor their conversation at various levels—pronunciation, morphology, and content—while simultaneously taking account of embedded nonverbal actions.

Childhood

In work considering aspects of learning how to talk beyond structural elements of conversation, we find both sequentially focused CA and membership categorization analysis (MCA). For example, the difficulties and challenges children face when interacting in unfamiliar circumstances are highlighted by Hutchby (2010) in counseling contexts, and by Cahill (2010) within medical interactions. The subtleties involved in inviting and encouraging a child's participation gain importance given O'Reilly's (2006) observation that adults are likely to simply ignore children's interruptions in family therapy sessions.

How children deal with challenging and problematic talk with each other is documented by Sidnell (2010) in his work on questioning repeats, commenting that children of different ages exhibit contrasting interactional concerns which cannot simply be accounted for by appealing to "internal" developmental mechanisms. Other work reminds us that children's own interactional concerns regarding role position can be evident in their talk (Gardner & Forrester, 2010). Forrester and Reason (2006), for example, highlight the sensitivity children exhibit surrounding membership categories of the self. Likewise, Butler and Weatherall (2006), using both sequential analysis and MCA, looked at the play activities of 6–7-year-old children and documented the subtle social pragmatic practices used by children, commenting that such situated cultural resources produce nuanced and creative versions of the world.

Such versions of the world are not fixed or determining, however, as is highlighted in the work of Danby and Baker (1998), whose analysis of preschool-aged boys' play "illustrates that masculinity is not a fixed character trait, but is determined through practice and participation in the activities of masculinity" (p. 151). The interdependence of talk and social positioning is also clear in Weatherall's (2002) research on children's recognition and production of gender roles. Weatherall makes the point that children of this age, as part of their striving to become competent members of their culture, show a particular sensitivity to the display of their knowledge of gender categories, and will correct inappropriate use of membership category terms. Finally, de Leon (2007) provides an illustrative example of how child-CA can illuminate our understanding of both conversational structure and childhood. His analysis of two young Mayan children's reorganization of greeting structures, playful repetition, and recycling across turns engenders an emergent sibling culture, one that "contests the social organization of the age-graded structure of the extended family" (p. 405).

CA research on children, on adult-child talk, and on topics germane to understanding how children learn how to talk is gathering momentum. Notwithstanding a degree of overlap, it is clear there are a number of identifiable themes in the literature. What is distinct about child-CA is the careful focus on how, why, and under what conditions younger members of any culture gradually attain the skills necessary for producing those reflexively accountable sense-making practices that constitute interaction.

Conversation Analysis and Classroom Interaction

PAUL SEEDHOUSE

This entry discusses how conversation analysis (CA) has been employed to investigate interaction which occurs in second/foreign-language (L2) classrooms. The detailed, intensive study of interaction in L2 classrooms only took off in the 1960s with the advent of audio- and, later, video-recording technology. The first wave of development in the description and analysis of L2 classroom interaction was observation or coding schemes from the 1960s. A second major development was the use of discourse analysis (DA) from the 1970s. DA uses principles and methodology typical of linguistics to analyze classroom discourse in structural-functional linguistic terms. Seedhouse (2004) suggested that DA cannot portray the flow of the interaction because it is essentially a static approach which portrays interaction as consisting of fixed and unidimensional coordinates on a conceptual map. Since the DA approach was developed for first language (L1) classrooms and transferred for use in L2 classrooms, it had difficulty in portraying the extra dimension which distinguishes L2 classroom interaction from L1 classroom interaction. This is that language is the object as well as the vehicle of interaction. With the development of coding schemes and DA studies, from the 1980s, the importance of interaction as a vital element in the instructed L2 learning process became clearer.

Strong interest then emerged in applying a new methodology (CA) to the description and analysis of L2 classroom interaction. CA had developed in the 1960s, had no obvious connection with learning, and in its genesis dealt exclusively with monolingual English data. Publications then appeared which started to address the relationship between CA and L2 classroom interaction. The overall picture of the L2 classroom which emerges from the application of a CA methodology is that it is a very complex, dynamic, and fluid interactional environment. Pedagogy and interaction are intertwined in a mutually dependent relationship and we must examine the minute detail of the interaction to gain a full understanding of the instructed L2 learning process. Previously, for many years researchers in the area of language learning had shied away from examining the micro-detail of classroom interaction, regarding it as an excessively complex, heterogeneous, and particularly “messy” source of data. However, with CA it became possible to do this and studies have demonstrated that, as with conversation, there is also *order at all points* in L2 classroom interaction.

In general terms, then, CA studies have transformed our understanding of how L2 classroom interaction is organized and how this organization is related to a number of teaching and learning issues. A number of studies have examined in detail specific issues related to language classroom interaction from a CA perspective, revealing subtle interactional practices which transform our perceptions of L2 learners and teachers. Olsher (2004) demonstrates how L2 learners in small-group project work may complete sequential actions through gesture or embodied displays, revealing the importance of nonverbal aspects of interaction. Koshik (2002) reveals how teachers use the pedagogical practice of designedly incomplete utterances in order to initiate self-correction by learners. Carroll (2005) challenges the general perception of L2 novice learners as incompetent communicators, uncovering

their ability to make creative communicative use of their minimal linguistic resources and use sophisticated conversational micro-adjustments. Novice learners can precision-time their entry into interaction, recycle turn-beginnings to solicit the gaze or attention of partners, and use vowel marking as a resource for forward-oriented repair. Mori (2002) traces how a task-as-work-plan (which was intended to be a discussion with native speakers) is transformed into a task-in-process resembling a structured interview of question-and-answer exchanges. Markee (2000) portrays the progress of intersubjectivity during two tasks, one of which results in learner comprehension of the target item while the other does not. Appel (2007, p. 282) examines how L2 classroom interaction can be seen as a form of performance, and suggests that "verbal interaction in the language classroom can be seen as a reflexive mode of communication which uses some of the resources characteristic of performance to make language its special focus."

Employing a macro-perspective, Seedhouse (2004) applied CA methodology to an extensive and varied database of language lessons from around the world to tackle the question 'How is L2 classroom interaction organized?' The main thesis developed in this monograph is that there is a reflexive relationship between pedagogy and interaction in the L2 classroom, and that this relationship is the foundation of its context-free architecture. This relationship means that, as the pedagogical focus varies, so the organization of the interaction varies. However, this also means that the L2 classroom has its own interactional organization which transforms intended pedagogy into actual pedagogy. The concept of the rational design of institutional interaction is employed to identify the institutional goal as well as three interactional properties which derive directly from the goal. The basic sequence organization of L2 classroom interaction is presented, together with an emic methodology for its analysis. Seedhouse stresses the dynamic nature of context by exemplifying how the institution of the L2 classroom is talked into and out of being by participants and how teachers create L2 classroom contexts and shift from one context to another. The monograph portrays the L2 classroom as a complex, fluid, dynamic, and variable interactional environment and provides a concrete example of how CA methodology can be applied to an issue of interest to language teachers and applied linguists. In order to understand the relationship between interaction and the process of language learning, it is vital to understand how the interaction is organized.

There has been interest in how CA can be employed to investigate notions relevant to language teaching and learning such as communicative competence and interactional competence. Communicative competence had previously been presented as a fixed and static construct; as Mondada and Pekarek Doehler (2004, p. 502) point out, the traditional notion of competence is of "a phenomenon that is isolated from socialization processes." CA offers a very different view of the nature of competence. Instead of working from the static assumption that competence is something that one has a fixed degree of at a point in time, CA presents competence as variable and co-constructed by participants in interaction. CA also provides a means of exploring the variable ways in which such competence is co-constructed in particular contexts by the participants involved. "Competence cannot be defined in purely individual terms as a series of potentialities located in the mind/brain of a lone individual, but needs to be conceived of as a plurality of capacities embedded and recognized in the context of particular activities" (Mondada & Pekarek Doehler, 2004, pp. 502–3). Lee (2006) suggests that, whereas communicative competence has traditionally been viewed as the goal of L2 teaching, it can also be viewed as a precondition of L2 teaching. Seedhouse (2004, p. 241) shows how CA can reveal the current state of a learner's competence and the level that a learner is able to achieve when assisted. Hellermann (2007, p. 85) defines interactional competence as the "ability to co-construct appropriate linguistic forms, registers, and sequential routines in appropriate contexts in order to accomplish discursive practices." Studies such as Carroll (2005) portray how interactants with minimal

linguistic resources can nonetheless employ these resources skillfully and innovatively in interaction in L2. Such CA research, then, reinforces a shift away from a linguistic deficit model focused on individual performance toward a model in which communicative competence is seen to be co-constructed.

Studies have critiqued the notion of “task” employed by the task-based approach to language teaching and learning. A number of CA works (Mori, 2002; Mondada & Pekarek Doehler, 2004; Seedhouse, 2004) demonstrate that there can be significant differences between the task-as-work-plan (what is supposed to happen) and the task-in-process (what actually happens) and reveal learners to be active agents, who transform tasks-as-work-plans into tasks-in-process on a moment-by-moment basis. Mondada and Pekarek Doehler (2004, p. 505) therefore insist “that [tasks] cannot be understood as stable predefined entities.” Studies of task-based interaction have generally provided useful evidence of student–student interaction, as opposed to plenary interaction.

In a similar vein, CA has been employed to provide evidence of what actually happens during particular language learning activities. In recent years, the range of activities covered has become very diverse, expanding the knowledge and evidence base. Examples in the literature are of how language play emerges and is organized; the interactional practices of collaborative video-game playing; the vocabulary learning of one learner during conversations over a three-month period; the practice of “doing word explanation”; a microanalysis of gesture and speech used by a teacher during vocabulary explanations; yes/no questions in a teacher-fronted English as a second language (ESL) lesson; and reading classes and the co-construction of a quiz game.

A number of CA studies have explored the mechanism of repair in relation to L2 classroom interaction. This is a vital mechanism as far as second language acquisition (SLA) is concerned; as Markee observes, “Conversational repair is viewed by SLA researchers as the sociopsychological engine that enables learners to get comprehended input” (2000, p. 31). Liebscher and Dailey-O’Cain (2003) suggest that the different types of repair initiations employed by teachers and learners are reflexively related to their respective roles as teachers and learners. Hosoda (2006) relates the employment of repair trajectories to level of language proficiency, showing that this became relevant when one participant invited repair by another and when intersubjectivity was threatened. Jung (2004) shows how a learner employs repair initiation as a resource in production of vocabulary items. Koshik (2002) reveals how teachers use the pedagogical practice of designedly incomplete utterances in order to initiate self-correction by learners.

One area of CA research into language learning which is expected to grow considerably in coming years is that of longitudinal studies that document the development of interactional patterns in learners over time. Studies so far demonstrate the promise of this approach. Young and Miller (2004) conducted longitudinal observation of revision talk, noted that the participation framework changed over time, and “demonstrate processes by which the student moved from peripheral to fuller participation” (p. 519). Hellermann (2007) examines task openings by successful learners over a period of at least 18 months. He proposes (p. 91) that learning can be conceptualized as “the change in the use of resources and strategies for engaging in a particular aspect of social interaction.” Brouwer and Wagner (2004, p. 44) examine the development over a period of two months of a Japanese learner of Danish: “The differences between early and later encounters are found in the complexity of the emerging structures which build on earlier talk and topics and where increasing displays of understanding by both participants can be seen. Learning a second language, then, may be described in terms of increasing interactional complexity in language encounters rather than as the acquisition of formal elements.” These authors conclude that “instead of describing [the learner’s] change in use of linguistic elements alone, one can explain her progress in terms of interactional resources and how they are employed in the interaction

in collaboration with her conversation partner" (p. 45). Markee (2008) proposes a "learner behavior tracking methodology" which is able to track longitudinal L2 development. This methodology tracks how the "learning object" occurs in interaction and also portrays the process of learning via interaction.

An issue which is receiving increasing prominence is the question of what constitutes adequate primary data for CA studies of L2 classroom interaction. It has been argued that nonverbal communication and gaze are potentially important features of face-to-face interaction and that multimodality should therefore be incorporated into CA studies. Recent CA studies in the area of language learning which demonstrate the significance of nonverbal communication and gaze for our understanding of interaction include Lazaraton (2004), Olsher (2004), Carroll (2005), Mori and Hayashi (2006), and Seedhouse and Almutairi (2009). A number of these studies employ frames from videos together with overlays such as arrows and graphics which highlight the significance of nonverbal features.

Looking to possible future directions for CA research in classroom interaction, it is highly likely that it will examine a wider range of languages being learned and taught, using a wider range of teaching practices, activities, and issues, in a wider range of classroom contexts. It is also likely that multimodal analysis will become more common.

Conversation Analysis and Cockpit Communication

MAURICE NEVILE

Conversation analysis (CA) research on cockpit communication uses audio and video recordings of actual or simulated flights to explore the language and practices by which pilots establish moment-to-moment what is happening, who is doing what, who knows what, and what is to be done next, to perform necessary tasks to fly their aircraft. Major studies have examined how airline pilots routinely collaborate as a crew to fly commercial aircraft (Nevile, 2004a; Auvinen, 2009), and other studies have examined data from civil aviation (Melander & Sahlström, 2009) or military air operations (Nevile, 2009). This CA research falls generally within the interests of institutional talk and workplace studies, and has offered an alternative to the mostly experimental studies of communication from within aviation human-factors psychology.

The dominant line of research has shown how pilots, in various and situated ways, orient to and accomplish appropriate timeliness and sequential order of talk and action. In the cockpit it is critical to say and do things at the right time and in the right order, as outlined formally in procedures, flight manuals, regulations, and training. Particular actions for flight tasks are mostly relevant, or possible, only when particular other actions have been completed, and are known to be so. CA studies show how pilots establish and maintain a sense of what now and what next as they progress through flight tasks and flight events. For example, pilots can preface a turn at talk with “and,” and so present some new activity or task as connected and relevantly next (Nevile, 2006c). Pilots develop an ongoing sense of their conduct of their flight as a whole by making salient the sequentiality of their work when the officially prescribed wordings they are required to use can leave this implicit. A pilot can also preface a turn with “and” to prompt another pilot to perform an action which is due but not yet initiated (Nevile, 2007a). Rather than make conspicuous another’s possible lapse, *and*-prefaced talk presents the absent action as merely timely and occurring ordinarily next in sequence. Or, when conducting a checklist for a flight task or stage, one pilot might say “okay” or “thank you” in response to the other’s final call of “checklist complete,” to show that the “complete” call was itself heard and there is now a shared crew understanding that the checklist is closed and it is legitimate to move to a next action (Nevile, 2005a).

Pilots’ orientation to the significance of completion is evident also in the timing and production of their talk for performing tasks. For example, talk in the airline cockpit is tightly scripted in content, and is constrained in allocation of speaker and turn order. Sequences of talk are repeated many times over the course of a pilot’s career. Cockpit communication can be highly predictable and so is vulnerable to moments of overlap at the end of turns, when speaker change occurs. However, pilots avoid overlapping talk and allow one another’s talk to emerge complete and in the clear (Nevile, 2007c). Moments of overlapping talk can signal trouble in the flow of talk and action (Nevile, 2008). Pilots can also use prosody, such as rising and falling terminal pitch, to signal continuity or finality as they progress and complete tasks, for example when jointly conducting a checklist (Nevile, 2005b).

Figure 1 After turning on the autopilot, a captain points to the illuminated autopilot button and says "I'll take autopilot's in"

Lastly and importantly, pilots can physically embody their understandings of appropriate timing and sequential order for performing tasks (Nevile, 2004a, 2004b, 2005b; Auvinen, 2009; Arminen, Auvinen, & Palukka, 2010). For example, pilots delicately modify features of talk throughout its production (e.g., pauses, sound lengthening) to synchronize talk precisely with accompanying nontalk activities (e.g., turning a dial, pressing a button), and so ensure that verbal claims about task progress and completion (e.g., "that's set," "autopilot's engaged") are consistent with reality (Nevile, 2004a, 2004b). That is, when something is said to be done it must really be so at the time of saying. For some actions or events a pilot can signal the momentary and relative value for joint attention of a cockpit display (e.g., for altitude), or other location (out of the windows), by pointing at it in ways that are more or less visible to and witnessable by the other pilot (see Figure 1) (Nevile, 2007b).

There are other lines of inquiry, including how pilots communicate with parties beyond the cockpit, such as air traffic controllers. Pilots can design talk to include multiple actions within a single turn (Falzon, 2009), and must integrate external communication with their ongoing collaboration within the cockpit (Nevile, 2004a; Auvinen, 2009; Nevile, 2009). Another interest has focused on how pilots act according to relevant cockpit roles (e.g., captain, first officer, crew) and associated duties and responsibilities (Frankel, 2000; Nevile, 2001, 2004a). Pilots can use choices of personal pronoun to invoke and ascribe particular roles and present their continuously evolving understanding of who's who in the cockpit for performing tasks (Nevile, 2001, 2004a). Some pronouns are scripted in officially prescribed wordings (e.g., "my power levers"), but others modify or occur outside official wordings ("I'll have cruise power"). By varying pronominal choices pilots realize and make accountable formal roles in situ and moment-to-moment. Other research considers roles such as learner and instructor in pilot education (Melanders & Sahlström, 2009).

In the cockpit things do not always go routinely, and trouble or problems can arise. Pilots and others identify and deal with such moments by drawing on language, embodied activity and gestures, and material resources, for example to restore intersubjectivity and repair the temporal and sequential order of talk and action (Frankel, 2000; Nevile, 2007a, 2008; Bergmann, Nazarkiewicz, Finke, & Dolscius, 2008; Auvinen, 2009; Arminen et al., 2010). Features of cockpit interaction can create a context for error (Nevile & Walker, 2005), and the challenge of managing the participation and understanding of multiple and distributed parties can lead to mistakes and poor decisions (Nevile, 2009). CA can therefore contribute to aviation safety by informing investigations of aviation incidents and accidents. CA can offer detailed transcriptions and analyses of “black box” voice recordings to examine communication as a possible contributing factor (Nevile, 2006a, 2006b).

A recurring finding of CA research on cockpit communication is that although much of what pilots say is constrained by formally prescribed wordings for procedures, pilots must realize these wordings in situ in real time, and they commonly vary the “script” as it is occasioned to meet local and emerging contingencies. Flying an aircraft is a technical and task-driven activity, but it is also highly dependent on language and processes of social interaction.

Conversation Analysis and Communication Disorders

RAY WILKINSON

Introduction

A communication disorder can profoundly affect a person's ability to convey information to others and to produce a full range of social actions within conversation (such as requesting, offering, telling off, correcting, telling jokes or stories, etc.). It can have a significant impact on a person's social and personal identity and their ability to create and maintain interpersonal relationships. The investigation of communication disorders is important in order to be able to analyze their causes and the forms they take and, ultimately, to improve treatment for those affected. At the same time, analyzing how communication may break down or not function with normal limits holds out the promise of being able to tell us something about the workings of normal, non-disorder, communication and its components. Other approaches such as neuropsychology, for example, have long drawn on communication disorder data in order to learn about both normal and disordered functioning (Ellis & Young, 1996).

In recent years, the method and findings of conversation analysis (CA) have been increasingly drawn upon in the investigation of communication disorders. In the case of aphasia, a language disorder typically acquired following stroke and the disorder most studied using CA, this approach has also been used to implement and evaluate treatment (Wilkinson, Bryan, Lock, & Sage, 2010). This overview will discuss how CA has provided a new perspective within the field of communication disorders and how it has produced a range of findings about how these disorders impact on people's everyday social interactions.

Communication Disorders

Communication disorders can occur in both adults and children and can take many forms (see Kent, 2004). One class of communication disorder primarily involves the processes involved in the production or reception of the speech signal. For example, dysarthria, a motor speech disorder, can occur due to damage to elements of the speech production process such as those involved in articulation or respiration. It can occur as part of disorders such as Parkinson's disease or cerebral palsy. A second class of communication disorder involves impairments to aspects of the speaker's linguistic system and can affect, for example, vocabulary or grammar. These impairments may impact on the person's ability to understand spoken language as well as to produce it and can also affect reading and writing. Communication disorders of this type include aphasia, or specific language impairment (SLI) in children. A third class of communication disorder includes significant cognitive or intellectual impairments. Disorders of this type can occur in adults with dementia or in people with certain types of autism or of learning difficulties (referred to in some countries as "mental retardation").

Investigating Communication Disorders Using CA

CA relies as its primary data source on video or audio recordings of naturally occurring social interactions, in particular those interactions which involve talk. Analysis using this approach focuses on the social conventions and practices which participants in an interaction draw upon in order to produce talk and other conduct in interaction which is treated by recipients as coherent and meaningful. As such, CA brings quite a different methodological and conceptual approach to the investigation of communication disorders compared to more traditional approaches within the field.

For example, elicited data has formed the basis for much of what is known about individual communication disorders as well as for the planning and evaluation of treatment for those disorders. Tasks used to elicit data include asking the person with the communication disorder (PWCD) to name or describe a picture, read aloud, repeat words or sounds, produce a narrative, or enact a role play. While the control which such an approach provides has many positive features, there are also, however, significant concerns about the ecological validity of findings produced using this approach (Heeschen & Schegloff, 2003). For example, there are questions about how closely the person's performance on the task in a clinic or laboratory might reflect their performance in everyday social interactions, where the presence of other participants produces particular time pressures on communication and may affect how the person designs and produces their utterances. Evidence so far suggests that aspects of a speaker's language production, such as grammar, can display systematic differences when elicited within a test situation as opposed to being produced spontaneously within conversation (Beeke, Wilkinson, & Maxim, 2003; Heeschen & Schegloff, 2003). Also, close analysis of PWCDs within naturally occurring everyday interactions can highlight their often subtle use of a range of resources which are not available to them in the testing situation. These can include nonvocal resources (e.g., gesture, body movement, and eye gaze) and the resources provided by the material environment (including objects to act upon or point to) and the PWCD's significant others (such as shared knowledge and familiarity, which can often permit the recipient to infer meaning, even when the PWCD's contribution may appear to others as difficult to interpret). At the same time, however, analysis of how the PWCD carries out tasks in the clinical context, including therapy tasks, may provide insights into the nature of the speaker's interactional strengths or deficits (Gardner, 1998).

Other methods which have traditionally been drawn upon in communication disorder research include interviews and questionnaires, in particular where the aim is to collect more social and ethnographic information. Again, however, while such approaches can provide useful information, their reliance on the person's memory and insight into the phenomenon under question can be problematic. In the case of conversation in particular, using interviews or questionnaires risks uncovering only superficial details compared to the wealth of information that can be found through analyzing audio or video recordings of conversation alongside transcriptions of those recordings.

Insights into the Impact of Communication Disorders within Social Interaction

Insights which CA has provided into the impact of communication disorders on social interaction will be discussed here by focusing on four overarching themes which have emerged from the investigation of individual disorders.

One theme is that these interactions recurrently display some form of delay in the progress of the PWCD's contribution toward completion, or in the sequence of which that

contribution is part, or both. These delays are often caused by the activity of repair, that is, practices for dealing with troubles in speaking, hearing, or understanding (see Schegloff, 2000). Different disorders may recurrently display distinct patterns of repair in interaction. Within conversations involving a person with acquired dysarthria, for example, a regular repair pattern is that of other-initiations of repair by the conversation partner (Bloch & Wilkinson, 2009). It is evident from these repair initiations that the source of trouble for the recipient is often the poor intelligibility of one or more elements of the speaker with dysarthria's turn arising from that speaker's motor speech difficulties. In many types of aphasia, on the other hand, there is a preponderance of self-initiations of repair, particularly in the form of word searches by the person with aphasia (Laakso & Klippi, 1999; Helasvuo, Laakso, & Sorjonen, 2004). While recurrent features of repair initiation may differ between these two disorders, in both cases it is not uncommon for the first attempt at self-completion of repair by the PWCD to be unsuccessful and for other attempts to then ensue, entailing often longer repair attempts and delays than are typically seen in non-communication disorder interaction. This inability to achieve self-repair despite a prolonged attempt is one occasion in interaction when the PWCD's incompetence may be quite visible and indeed may be referred to or alluded to through, for example, laughter (Wilkinson, 2007). As well as often being longer, repair in these interactions may also be more jointly achieved than in non-disorder interaction. Even when the eventual outcome is self-repair by the PWCD, the conversation partner will often have been actively involved in the repair activity leading up to that successful outcome.

A second research theme is a focus on how the disorder can be seen to impact on the PWCD's social identity, interpersonal relationships, or both. Kitzinger and Jones (2007), for instance, show how the memory deficits associated with Alzheimer's disease, a form of dementia, may have interactional consequences for family relationships. For example, in forgetting to inquire about certain features of family members' well-being at a point when such an inquiry might be expected (e.g., in the "how are you" sequences in the openings of phone calls), the person with dementia may be viewed, quite incorrectly, as self-centered and uncaring about the relationship concerned. In relation to social identity, Antaki, Walton, and Finlay (2007) observe a recurrent practice whereby staff working with people with learning difficulties, for example in residential homes, regularly propose an activity for the residents (e.g., going cycling) in terms of social aspects, such as which other people will be present. Antaki et al. (2007) discuss how this practice implies a limited identity in that, for example, the interest of the people with learning difficulties is treated as being primarily social, with less interest in the activity's intrinsic qualities. Another feature of identity in communication disorder interaction can be highlighted using Goffman's (1981) distinction between the "author" of an interactional contribution (i.e., the person who, broadly speaking, has chosen the words) and its "animator" (i.e., the "sounding box" through which the words are actually produced). While in a non-communication disordered speaker these two aspects are regularly—although by no means invariably—combined, in PWCDs there is often a systematic separation between author and animator. For example, in his analysis of interactions between Chil, a man with severe aphasia, and his everyday interlocutors, Goodwin (2007) shows how, despite having only three words at his disposal (*yes*, *no*, and *and*), Chil is able to use practices such as other-initiation of repair to prompt others to alter what they have just said and thus produce, or "animate," utterances whose meaning Chil can in some sense be seen to have "authored." Wilkinson, Bloch, and Clarke (in press) analyze a different type of separation between author and animator, that is, the use of voice output communication aids (VOCAs) by PWCDs, for example those with severe dysarthria, to "speak," or "animate," a contribution which they have authored (by means of, for example, a keyboard). In both cases, while animation allows the PWCD to produce a more complex contribution than would otherwise be possible, there can also

be costs. The PWCD, for example, may have less control over the message they wish to convey or over the stance and aspects of self-identity which they may want to project via their contribution.

A third theme, linked to the above, concerns how the PWCD, other participants, or both adapt the way in which they produce their contributions in response to the limitations brought about by the communication disorder. One form this takes is that two (or more) participants may systematically co-construct an element of talk which in non-disorder interaction would typically be produced by one speaker. Heeschen and Schegloff (2003), for example, analyze how in their data the use of “telegraphic speech” (grammatically simplified expressions) by a speaker with aphasia prompts the interlocutor to unpack the verbal and nonverbal contributions of the person with aphasia and co-produce in systematic ways what that speaker was trying to articulate. Bloch (2005) analyzes a case of co-construction at an even finer level of granularity; the co-construction of individual words by a man with severe dysarthria and an everyday interlocutor (his mother). In this case, due to the man’s poor level of speech intelligibility, the dyad had evolved a system of talking whereby the man regularly produced a word one sound (or phoneme) at a time, with his mother repeating back to him her hearing of that sound to ensure she had heard it correctly. This carried on until the word was complete.

The fourth theme concerns how analyses of a PWCD’s utterances, and in particular their responses within interaction, may tell us something about the nature of the intelligence, comprehension, or both of that person and, by extension, of other people with a similar disability. In an analysis of a man with frontotemporal dementia, for example, Mikesell (2009) shows that his responses recurrently displayed an inability to understand the intention of the interlocutor’s prior utterance and the ongoing activity sequence of which that utterance was part. Maynard (2004) examines responses produced by people with autism on a published educational test and uses these data to investigate the nature of intelligence in autism. He shows how the children with autism in his data produce responses which display a local, or literal, understanding of the subtest question rather than the kind of gestalt or composite understanding which would commonsensically be expected. Maynard’s paper is one example of CA research in this field which not only discusses its findings in terms of what has been learned about the communication disorder under investigation, but generalizes outward to discuss what has been learned from the analysis about aspects of everyday social life, such as deviance and disability and everyday language practices. This use of communication disorder data to learn about “non-disordered” speech, language, and cognition within interaction constitutes one direction which research in this field may be expected to pursue further.

Conversation Analysis and Design

BEN MATTHEWS

Since the mid-1980s, the design of various technologies such as user interfaces for photocopiers, surgical monitoring alarms, London Underground control systems, video-conferencing software, and interactive museum exhibits has benefited from investigations informed by conversation analysis (CA). The exemplar studies which form the basis of this entry are best understood as contributions of CA-informed work, rather than contributions to the discipline of CA.

CA (and ethnomethodology more generally) first came to the attention of those concerned with the design of technologies through the significant work of Lucy Suchman (1987). Her analysis of the difficulties that users encountered trying to work a photocopier had a profound impact on the field of interface design (which has since become known as interaction design—designing the interactions with and of technologies). A number of general features of CA make it ideal for application to technology design, not least because it offers a clear counterpoint to other approaches that attempt to explain human interaction with technological systems. Prior to Suchman's work, cognitive science and experimental psychology were the human sciences that had the largest influence on how designers sought to understand and predict how users would behave with technology and interpret *its* behavior (Norman & Draper, 1986, is representative). In contrast to such approaches that advanced general abstract models of human behavior, or that accumulated quantitative empirical findings on the basis of controlled experiments of users interacting with systems, CA proposed something completely different. CA offers the promise of a systematic, evidence-based investigation of the interactional difficulties encountered in the use of technology, detailing the many and varied resources that users employ in order to understand, and render intelligible, actions with and of technology. CA supplants a generic model of human sense-making processes with an analytic orientation to practice that can reveal users' own local, situated methods for deciphering system behavior, exchanging controlled experimental settings for people's naturally occurring interaction with systems.

To this end, CA-informed studies have provided a number of contributions to systems design. The following examples, although selective, are representative of this growing corpus of work. One of the principal contributions of Suchman's (1987) study was to lay out, in an analytic scheme, the multiple mismatches that obtain between the resources available and employed by the users to make sense of the system's behavior, on the one hand, and the resources upon which the system can rely in order to respond to the users' actions, on the other. Her analysis showed how the users make use of all manner of elements in their social, temporal, and material environments (including the sequence and structure of the system's actions within the users' courses of activity) as resources to help them decipher the system's responses and instructions. In contrast, the system could only produce automatic responses from users' overt actions with it. To complicate matters, these automatic responses often obscured, rather than revealed, the design rationale on which they were based, as the users received and interpreted each system response in relation to its placement in a socio-material sequence of interaction that gave each system response a locally contingent sense. Suchman's recommendations for systems design included

expanding the resources on which systems could draw in order to respond to users' commands. Importantly, however, Suchman's work is best known in design less for its CA orientation or for its design recommendations than for its trenchant critique of rationalist models of human action that were embedded within computer engineering cultures, and upon which the design of "intelligent" interfaces were based. Her critique, coupled with its empirical diagnosis of the alien intelligibility of the photocopier interface, is responsible for the remarkable legacy that CA-informed work has enjoyed in design circles. Notably, that legacy includes the widespread recognition of the importance of the social and material *context of use* to the usability of interaction technologies.

Subsequent CA studies of technology can be seen to have followed Suchman with respect to the types of contributions they offer to design. Roughly speaking, these contributions can be divided into (a) articulation of the social organization of work and life; (b) enumeration of design cautions, recommendations, or specifications; (c) development of "hybrid" design practices; and (d) respecification of central concepts in design research.

The Social Organization of Work and Life

The work of Christian Heath and Paul Luff since the early 1990s deserves particular mention. Their collection of studies (Heath & Luff, 2000) has served as a benchmark for the contribution of a CA orientation to an understanding of collaborative work involving the use of technologies. For instance, the ways in which a user's actions with and orientations to a system are publicly available to her colleague can be a vital resource for the colleague's coordination of his actions with hers, and for the accomplishment of their shared tasks (Heath & Luff, 1991). This bears on the many attempts by designers to develop computer systems to support online collaboration through video conferencing or shared virtual workspaces, as many of these systems, through their design, prohibitively deny users access to precisely these resources. The multiplicity and variety of users' sense-making resources cannot simply be encapsulated within systems, or easily made available to systems as input. This general point has been reinforced and developed in subsequent CA-informed studies in a range of different settings, including air traffic control (Harper, Hughes, & Shapiro, 1989), collaborative virtual environments (Hindmarsh, Fraser, Heath, Benford, & Greenhalgh, 2000), electronic guidebooks (Szymanski, Aoki, Grinter, Hurst, Thornton, & Woodruff, 2008), technical support systems (Whalen & Vinkhuyzen, 2000), and software tools for designers themselves (Bowers & Pycock, 1994), among others. In each case, these studies have offered detailed understandings of technologically mediated (and disrupted) practices in the lived detail of their enactment that have formed an important resource for the redesign of the technology in question.

Design Cautions, Recommendations, and Specifications

Practically, CA contributions to the actual design of systems have included recommendations for the kinds of changes systems should make (and should avoid making) to existing work practices (Button & Harper, 1993), or for implications for staff training and expertise (Whalen & Vinkhuyzen, 2000), or, more ambitiously, for specifying the nature of technologies and their features. For instance, on the basis of their studies, Heath and Luff (1992) proposed that computer-mediated communication systems would better support cooperative work if users were given the freedom to systematically control, while an activity is already underway, their own audiovisual accessibility to their collaborators. (This has, years since, become a feature of technologies such as Skype®.) Work conducted at PARC has perhaps taken the contributions of CA to design the furthest in this regard,

where CA observations have informed specific design features of an electronic guidebook at an historic house. After study of the structure and content of the social interactions of visitors using these devices, a new design was developed that allowed visitors to “eavesdrop” on the audio content playing on their friends’ guidebooks (Szymanski et al., 2008).

A more controversial application of CA to systems design has been the move to operationalize the findings of CA with regard to the systematic organization of ordinary conversation as specifications of formal rules for the behavior of more “natural” text and speech system interfaces (Luff, Gilbert, & Frohlich, 1990). While there remains promise for some kind of application of CA to speech and text interfaces in this way (and certainly, some interesting systems have been developed as such), the claims made on behalf of such “conversing systems” have generated some dispute among conversation analysts (Button, 1990; Button & Sharrock, 1995).

Development of “Hybrid” Design Practices

One of the enduring legacies of CA approaches to the study of technologies for design has been the development of “hybrid” design practices. Although this began in the late 1980s with designers taking an interest in ethnography (and the social sciences more generally) for the purposes of informing design, it developed into more specific, engaged forms of multidisciplinary participation. In this respect, while CA studies have certainly informed design, helped determine technological design features, and reworked notions in design discourse, they have also been an essential component in the evolution of design practice itself. For example, Suchman and Trigg (1991) developed a practice of using video as a medium for designers to reflect on their own ways of working. On the basis of collaborative experiences with the application of CA in design and technology projects, Jordan and Henderson (1995) introduced the idea of multidisciplinary interaction analysis laboratories. A range of approaches for integrating an ethnomethodological orientation into design projects has been undertaken and described (Dourish & Button, 1998), and practical strategies for integrating CA into technology design have been developed (Woodruff, Szymanski, Grinter, & Aoki, 2002).

Respecification

In a different vein, CA-informed studies have also changed the ways in which design research has conceptualized a number of topics central to its practice. A number of these contributions have served to erode inherited distinctions. Heath and Luff’s (1991) analytic work undermined conceptual divides between the individual and the social in the accomplishment of cooperative work. Similarly, the maintenance of a strong distinction between the social and technical has been subjected to repeated attack in these studies: Users’ actions with systems are always actions-in-a-social-field, and system responses must equally be understood within the social and temporal organization in which they are irredeemably implicated. Similarly, a number of other notions, including context (Dourish, 2004), coordination (Heath & Luff, 1991), rules (Button, 1994), abstraction (Dourish & Button, 1998), generalization (Sharrock & Randall, 2004), and human and artificial agency (Suchman, 2007), have received CA and ethnomethodological scrutiny. Design research has subsequently become a new arena for debates between different schools within the social sciences (Nardi, 1996), a development that has been formative for the sophistication of theoretical discourse in design research more generally; see, for example, Suchman’s (1994) critique of speech act theory as a reliable basis for the design of systems, and the special issue of *Computer Supported Cooperative Work* (1994) dedicated to the responses it generated.

Conversation Analysis and Dyads, Triads, and More

MARIA EGBERT

Introduction

In early sociological work Simmel (1902) first approached the relationship between group size and the possibility of different kinds of affiliation and opposition. Later, Goffman (e.g. 1961) explored how in groups of varying size diverse sorts and degrees of participation are possible. Seminal to later conversation analytic (CA) research has been Goffman's concept of "situation" or "participation framework" as "an environment of mutual monitoring possibilities, anywhere within which an individual will find himself accessible to the naked senses of all others who are 'present', and similarly find them accessible to him" (Goffman, 1972/1964, p. 63). CA has examined the interactional activities in participation frameworks in which the number of participants is related to the interactional outcome, depending on whether a person is in interaction with another person, in a triad, or in a participation framework with four or more persons.

Dyads

Dyads are the only group in which the departure of one member ends the interaction; it is the only constellation in which there can be no minority or majority; and even in this smallest social group there can be agreement or dispute (Simmel, 1902).

A gathering of two participants forms a "fully-focused gathering" (Goffman, 1961, p. 91), as long as there are no external factors to which a member orients. The ringing of the telephone may lead to a temporary second focus, while the continuation of the first conversation remains relevant and imminent. When a third person is in the realm of mutual monitoring, a simultaneous involvement of one member with the third person may occur, holding the engagement in the suspended first interaction through body posture (Schegloff, 1998). In such a torque position, the body below the waistline indicates the "base" involvement in the main interaction, while the turning of the torso or head to the other co-present person signals temporary involvement, thus turning the encounter into what Goffman (1961) termed a "multifocused" gathering.

Dyadic interaction has been conceptualized as a model of multi-person constellation in order to gain an understanding of the specifics of groups with more than two participants. Differentiating between "party" and "person," Schegloff (1995) demonstrates that the turn-taking mechanism is designed to organize "the distribution of talk not in the first instance among persons, but among *parties*" (p. 33, Schegloff's emphasis). This applies to other practices in multi-person interaction. In multi-person storytelling, participants regularly organize themselves into two parties, with the storyteller and sometimes a co-teller as one party to whom the story recipients align in such a way that they display listenership through body position, eye gaze, and verbal reciprocity and thus form the other party (Goodwin, 1981, 1984). In many institutional settings this underlying dyadic principle is readily observable

in the organization of the physical environment, such as in classrooms, courtrooms, and some churches.

Triads

In triads, two participants can form a coalition against one, and conversely, in a conflict between two, a third participant can help in conflict resolution (Simmel, 1902). CA reveals how affiliation and disaffiliation are achieved interactionally.

Sacks discerns for triads (and larger multiparty interaction) that one person's action can serve different purposes to those of the other two.

Consider the case of two guys and a girl in a place together. If she flirts with B, then she may be seen as teasing C; . . . That is to say, she may have no interest in flirting with B, she may be interested in teasing C. (Sacks, 1995/1969, Lecture 2, p. 100)

Similarly, a compliment can be designed to affiliate or to partition. A compliment may indirectly devalue the non-addressed third coparticipant, whereas a "safe" compliment does not implicate the non-complimented coparticipants negatively (Sacks, 1995/1969, Lecture 2, p. 103; Golato, 2005). In dyadic interaction the compliment sequence is complete when the addressee delivers a response (Pomerantz, 1978); in triads it is just as likely that the third participant steps in and produces a second compliment agreeing with the first compliment (Golato, 2005). Special features of triads also occur in complaints. In dyadic interaction the addressee of the complaint usually reacts with an account, with a justification, by delaying a response, or by disattending to the complainable (Mandelbaum, 1991). In multiparty interaction the gap emerging frequently after the delivery of the complaint is sometimes used by a third participant to step in and to dissipate the tension associated with the complaint (Egbert & Vöge, 2008). In interactions with three persons hierarchy may pose specific problems when status is indexed linguistically. Research on Pohnpeian, a Micronesian language, shows how in a single turn, a speaker can orient to two separate levels of rank; in addition, one participant's status can be differently oriented to by two different speakers in the same conversation (Keating, 1998). Many more kinds of triadic participation frameworks are documented, such as byplay (Goffman, 1981; Goodwin, 1997), cross-play (Goffman, 1981), talking for the overhearer (Heritage, 1985), and forming collectivities (Lerner, 1993; Egbert, 1997a).

The addition of a third person to a dyad can contribute to conflict resolution and a stronger union of the prior dyad (Simmel, 1902, pp. 45–6). This feature is the basis for special kinds of institutional interaction. In couple therapy there is a tendency toward body posture constellations in which the couple align in a parallel position to each other and together face the third participant (Schefflen, 1964). However, affiliation can also be formed in a different way. When a patient in a medical setting is accompanied by a third person—for example, a child by a parent—the doctor and the person accompanying the patient often disregard the patient's experience of the illness, a phenomenon which does not necessarily seem to be related to the patient's young age alone (Schwabe, 2006).

Differential levels of participation have also been found for triads in which interactants have differential communicative resources. Bolden (2012) shows this for Russian immigrant families to the USA. In interactions with at least three participants one of them assumes the role of, or is invited to serve as, a language or culture broker in order to mediate when problems of mutual understanding occur. In Charles Goodwin's research on interaction with an American aphasic man whose only linguistic resources are the words "yes," "no," and "and," the participant with aphasia uses the talk of others to perform a variety of

actions (Goodwin, 1995). In language socialization, the triadic structure can serve particular purposes. For Navajo, Field (2001, p. 256) reports that in

using triadic directives, adults simultaneously accomplish two interactional goals: they get the indirect target to perform some action, and they also prompt the intermediary peer or sibling to take responsibility for their peer or younger sibling. Thus, the triadic participation structure of these directives diverts authority onto a child peer (often an older sibling), providing him or her with a culturally appropriate social role to step into, and reinforcing traditional expectations concerning relations between peers and self-determinacy among children as a peer group—for example, that they are expected to be responsible for each other.

Two interactants may also engage with nonhuman beings, such as pets, things, and ghosts, thus constructing a participation framework which utilizes some of the features of human triads. In a veterinary clinic the veterinarian and staff may address “the animal as though it were able to engage in purposeful action”; people “attend to and affiliate with animals”; they produce talk “voiced on the animal’s behalf”; and they also use talk to animals “as a resource to smooth the way for ongoing professional (and interpersonally cordial) interaction” (Roberts, 2004, p. 424). Not only animals but also technological devices may be oriented to in ways exploiting specific features resembling a person. A study of two persons visiting a museum shows the role which an electronic museum guide (a recorded voice audible through headphones) can play. In their turn taking the two interactants orient to this technological device as if it were a third participant (Woodruff, Szymanski, Grinter, & Aoki, 2002). Anthropologists and conversation analysts report of many communities of practice that ghosts and spirits (not detectable by most Western researchers) are oriented to by humans as coparticipants of a participation framework (e.g. Everett, 2008). Such research indicates that the members’ perspective on the participating framework and the number of participants in it may differ from the researcher’s counting.

Interactions With Four or More Participants

The key function of a group larger than three is “that it makes possible the subdivision of a group into minor groups” (Simmel, 1902, p. 189). Initial observations on single-case analyses (Sacks, Schegloff, & Jefferson, 1974, p. 713) show that with a minimum of four participants, a conversation can temporarily split up into two parallel conversations (schisming) and come together again (merging). From a video analysis of everyday conversation, Egbert (1997b) examines in detail how through all the coparticipants’ coordinated actions these transformations are achieved. Concerted actions are needed because it takes at least two coparticipants to break away while a minimum of two others is required to maintain the already ongoing conversation. While sustaining schisming, coparticipants orient to the respective other parallel conversation in specific ways, including poetics across sub-conversations, eye gaze, and switching between sub-conversations. Thus schisming can only be fully understood by taking into consideration the Goffmanian concept of participation framework. As a social action, breaking away from an ongoing conversation into a parallel conversation achieves affiliation with the other breakaway partner(s), and at the same time the remaining conversationalists are disaffiliated. An examination of schisming can also discover a relationship to categories beyond talk. The fracture achieved in schisming may coincide with membership categories, such as generation, gender, host–guest, and in bilingual settings along language lines.

In many institutional settings the breakaway conversation is done as subordinate to the already ongoing interaction, which usually follows an agenda. This is the case in classrooms,

meetings, and the courtroom, where extended and unrestrained breakaway actions can be sanctioned in order to return to a joint focus which is needed to perform the institutional task (Goffman, 1961; Atkinson, 1979).

For interactions with more than four coparticipants, CA studies usually focus on specifics of the group settings other than number of participants. There is a tendency, with an increase in number of participants, for the group to more likely be organized formally to ensure unity (Simmel, 1902). Examples are classrooms, business meetings, and religious rituals.

The number of participants is one of many features of a setting. In order to fully understand a situation, research needs to appreciate the multidimensional nature of interaction as a situated activity. The overall conclusion to be drawn from the investigation of how number of participants is related to interaction is that humans are in the first place social beings with a concern for union and separation.

Conversation Analysis and Education

TOM KOOLE

Introduction

Conversation analysis (CA) has been concerned with education from an interest in how educational practices are accomplished by participants as situated activities. First and foremost this has meant an interest in interaction in classrooms as the primordial site of formal education. Conversation analysts aim to analyze how teachers and pupils establish “order” in the classroom; not order as the pedagogical teacher problem of how to keep pupils from disruptive behavior, but order in the sense of bringing about classroom interaction in such an “orderly” manner as to become recognizable and interpretable as classroom interaction, both for teachers and pupils as participants, and for us as observers and analysts. And when the issue of pedagogical order and teacher authority does get analyzed, as in Mehan (1979) or Macbeth (1990), it is dealt with as an instance of the latter type of “order,” not as a unilateral teacher problem, but as an interactional accomplishment of both teacher and pupils.

Although CA has also produced studies of student group work (Ford, 1999; Melander & Sahlström, 2009), teacher–student dyads (Koole, 2010), and student–student dyads (Hellermann, 2008), the interest in the orderly production of classroom interaction has primarily focused on frontal teaching to the whole class. Two basic organizational features of informal talk-in-interaction have also been important foci of CA studies of education: *turn management*, or how teacher and pupils organize their mutual speaking and listening, and *sequential organization*, with an interest in the interactional organization of classroom activities. Recent studies show an increasing interest in learning as an interactional activity and an interest specifically in teaching second language classes.

In studying these organizing features, a research interest has been the relation between classroom interaction and informal face-to-face conversation. CA takes informal conversation to provide a basic set of interactional norms and resources, some of which can be adapted for institutional practices, while others remain intact. The CA treatment of classroom interaction shows a long line of studies of the relation between informal and educational interaction, some arguing that basic principles have become adapted to institutional practice (e.g. McHoul, 1978, on turn taking; Mehan, 1979, on sequence organization), some showing that basic principles are incorporated into classroom practices (e.g. Hellermann, 2003, on syntax and prosody as interaction organizing resources; and Lerner, 1995, Koshik, 2002a, 2002b, Margutti, 2006, and Koole, 2010 on question–answer relations), and some disputing whether similar phenomena from informal and classroom interaction should be seen as adapted or different (e.g. McHoul, 1990, and Macbeth, 2004, on repair and correction).

Turn Management

Sacks, Schegloff, and Jefferson in their 1974 paper on turn taking had already suggested that in different institutional contexts we would see different means for allocating turns that

2 CONVERSATION ANALYSIS AND EDUCATION

can be described as deviations from the turn-taking systematics of informal conversation. This challenge was taken up by McHoul (1978) when he analyzed teachers and pupils as having asymmetric turn-allocation rights. This amounted to a systematics that is a modification of the Sacks et al. (1974) model for informal conversation in two major respects. In contrast to informal conversation

1. pupils may not self-select after each turn-completion point of the present speaker, but must wait to be selected by the teacher; and
2. pupils do not have the right to select a next after they complete their turn, the teacher is always the next speaker.

Since 1978, however, conversation analysts have found student self-selection to be much more ubiquitous than could be predicted from McHoul's analysis (e.g. Sahlström, 1999). A major classroom technique for turn allocation is a conditioned form of pupil self-selection whereby a teacher invites all pupils to take a turn or bid for a turn (Mehan, 1979; Mazeland, 1983). In excerpt (1) we see both turn-allocation techniques.

(1) [Mazeland (1983)]

- 01 TEA: wie heeft er nog wel jaartallen verder dan driehonderd
who has heard of any years beyond three hundred
02 voor Christus gehoord.
before Christ
03 PUP: ja, zeshonderd jaar voo[r Christus
yes, six hundred before Christ
04 TEA: [zeshonderd jaar voor Christus.
six hundred before Christ.
05 TEA: weet jij iets van zeshonderd jaar voor Christus?
do you know anything of six hundred before Christ?

In lines 1–2 the teacher invites pupils to self-select by asking a question addressed to all pupils with “who.” In line 5, subsequently, the teacher selects a single student, addressed with “you” (sg.), for a next turn.

An important focus of CA studies of turn management in classrooms has been on teacher techniques for allocating turns. In his influential study “Learning Lessons,” Mehan (1979) was concerned with the difference between “individual nominations” (as in excerpt 1, line 5) and whole-class-directed invitations in particular “invitations to bid,” for example by raising a hand, and “invitations to reply” by self-selecting (excerpt 1, lines 1–2). Others have focused their analytical attention on the design of teachers’ turn-allocating turns (Lerner, 1995; Koschmann, Glenn, & Conlee, 2000; Koshik, 2002a; 2002b). A teacher-turn format that is often used in classrooms is what Koshik (2002a) calls the “designedly incomplete utterance”: The teacher produces an utterance that is designed to be completed by a pupil.

In comparison to the research on teacher-allocation techniques, much less attention has been given to the work pupils do to get turns. Yet the studies that exist convincingly demonstrate pupils’ active hand-raising behavior (Sahlström, 1999) or verbal bids, often in combination with hand raising, as techniques for getting turns, or the opposite: They may do work to avoid getting turns. Sahlström (1999) discusses the example of Sven, who only raises his hand at places where the teacher’s turn is audibly not yet complete, and as a result does not get a turn.

Sequence Organization

The sequential structure that has, without question, received most attention in studies of classroom interaction is the IRF sequence. In this sequence, first analyzed extensively from a CA perspective by Mehan (1979), a teacher performs an initiative action (I: initiation), the pupil responds to that initiative (R: reply), and the teacher then provides feedback to that response, often an evaluation (F: feedback). This sequence may be used as in excerpt (2) where a primary school teacher instructs pupils to move their seats, and subsequently evaluates the move as “good.”

(2) [Mehan (1979)]

01 TEA: these four people over to Martin
 02 PUP: ((*move to seats*))
 03 TEA: good Rafael

And it is used very ubiquitously to discuss educational content, as in excerpt (3), where a mathematics teacher and a pupil look at the axes of a coordinate system.

(3) [Koole (2010)]

01 TEA: hier nemen ze stapjes van?
 here they take steps of?
 02 PUP: tien
 ten
 03 TEA: ja.
 yes

Here, the teacher asks a question, the pupil answers that question, and the teacher evaluates that answer as correct. The third turn shows that the teacher knew the answer to his own question, and for that reason these teacher questions are also known as “known information questions” (Mehan, 1979).

The IRF sequence consists of three related sequential “positions” (I, R, F), but not necessarily of three turns. A sequence can be expanded to include more turns, as in excerpt (4), where the teacher’s negative evaluation in line 3 induces the pupil to correct her first answer. Only after the pupil’s answer in line 4 receives a positive evaluation (line 5) does the sequence come to a close.

(4) [Koole (2010)]

01 TEA: juist, wat is hier het kleinste getalletje?
 Right, what is the smallest number here?
 02 PUP: zes (.) tien
 six (.) ten
 03 TEA: nee,
 no,
 04 PUP: tien, tien
 ten, ten
 05 TEA: tien
 ten

The I–R Relation

CA research of this IRF sequence has produced several educationally relevant insights into the relation between the three sequential positions. As far as the relation between Is and Rs is concerned, the question at stake is how particular types of teacher Is make pupils respond with particular types of Rs. One of the earliest findings in CA is that we overwhelmingly organize our talk as action pairs called “adjacency pairs” (Schegloff, 2007), such as a pair of greetings, or question–answer pairs. The two parts of such pairs are produced by two different speakers, which makes the production of a first-pair-part an appropriate tool for turn allocation. Following a first-pair-part, speaker change needs to occur. Second, the pairs are type-governed. A greeting needs a return greeting, and a question needs an answer. Moreover, this relation between questions and answers has been discovered to be so specific that particular question formats project particular types of answers. Not only does, for example, a *why*-question project a reason-answer and a *where*-question a location-answer, but, more interestingly for educational practice, questions with built-in answer options commonly project one of the options as the “preferred” answer (Schegloff, 2007).

The most common question of this type is the yes/no question, with its two answer options “yes” and “no,” and these yes/no questions very frequently embody a “preference” for either a “yes” or a “no” answer. This feature of yes/no questions is used as an educational resource in producing the first position of the IRF sequence. Koshik (2002b), for example, found that teachers use yes/no questions that prefer no-answers to point essay-writing students to problematic aspects in their writing.

(5) [Koshik (2002b)]

- 01 TEA: are you gonna talk about it? in relation to: de Gaulle?
- 02 STU: (this) nuh uh. heh:=
- 03 TEA: =not right here right?
- 04 STU: yeah

In excerpt (5) the teacher question in line 1 indicates for the student that at this point in his essay (“in relation to de Gaulle”) he was not supposed to talk about “it.” We see the student in his response treat the question indeed as introducing a problem, and the teacher confirms this in line 3. Margutti (2006) and Koole (2010) show that this use of question preference for educational purposes is present in several other types of questioning, such as questions with two answer options (“up or down”; “mountains or plains”) of which one is the preferred option.

The R–F Relation

Another line of research has focused on the relation between the last two sequential positions, R and F. Hellermann (2003) noticed that teachers often evaluate student answers by repeating that answer. Prosody is used in these evaluations to distinguish repetitions that make a positive evaluation from other repetitions. McHoul (1990) compared teacher evaluations of pupil answers to the Schegloff, Jefferson, and Sacks (1977) analysis of repair in informal conversation, and found on the one hand that in educational contexts also there is a preference for self-initiation and self-correction of errors, while on the other hand other-initiations and other-corrections—by the teacher—are more frequent than in informal contexts.

Conclusion

The study of the situated accomplishment of educational order has been exemplified here with studies of turn management and sequential organization, two basic organizing principles of both informal and classroom interaction. These studies show that classroom interaction is related to informal conversation in ways that are educationally relevant, and in return can provide insights into the nature of informal talk. This relevance for application is not always immediately embodied in the research outcomes, sometimes because of the actual distance between analysis and application, sometimes also because analysis needs to be translated into application. Let us conclude with an example of the latter. Given the preference embodied in a yes/no question for either “yes” or “no,” teachers are better advised to apply such questions in activities that seek to convey information to pupils than in activities that seek to check pupils’ understanding; or, to phrase it tangentially, teachers are better advised to treat such questions and their answers as a means for conveying knowledge than as a means for checking it. The preference norms that inform these question–answer relations are examples of a normative interactional organization that, in contrast to for example the norms for turn allocation, are directly incorporated from informal conversation into classroom interaction to accomplish educational order.

Conversation Analysis and Emergency Calls

JAKOB CROMDAL

Calls for emergency assistance are operated by a range of organizations across the world, including local police authorities, medical institutions, and dedicated dispatch centers. Conversation analysts have long taken an interest in exploring the organization of such calls, seeking to understand how the general principles of turn taking are modified to meet the social and institutional concerns of seeking and providing help (Whalen & Zimmerman, 1987). Specifying how institutional contexts are reflexively tied to the parties' local production of trouble reports, this work came to pave the way for a wider body of research on service-related telecommunications (see Baker, Emmison, & Firth, 2005).

Overwhelmingly, emergency calls stand out for their brevity and narrow focus, forming a class of highly specialized and goal-oriented institutional talk. According to Zimmerman (1992), emergency calls are typically organized into five distinct phases: (a) opening and identification of the service; (b) request for assistance; (c) interrogative series; (d) response; and (e) closing. It is fair to say that the opening exchanges have received far more research attention than the other phases of the calls, which points to the procedural significance of the initial alignment of the business and concerns which each party brings to the interaction (Whalen & Zimmerman, 1990; Cromdal, Osvaldsson, K., & Persson-Thunqvist, 2008). One important feature, at the operator's end, is a pre-beginning orientation toward every call as a virtual emergency. The specialization of the call, while being continually achieved in the talk, is hearable already in the opening line, through which the operator identifies the institution as, specifically, an emergency assistance service. Also, the initial talk is characterized by topical reduction: greeting exchanges and other mutual courtesies typical of ordinary telephone calls give way to strictly service-relevant matters. The resulting organization of the opening exchange—where the identification of the service creates a topical slot for a functional request for help—is fundamental to the parties' "achieving an institutionally constrained focus to the talk" (Whalen & Zimmerman, 1987, p. 175) from the outset.

Inquiries into the practice of interrogation have explored how parties deal with matters of detail and veracity in callers' accounts of various incidents as well as the organizational relevance of this information (e.g., Sharrock & Watson, 1989). Callers, who may often have access to first-hand observations of the reported incident, are normally unfamiliar with the institutional rationalities and procedures of dispatch work. The work of emergency operators is therefore guided by an interrogative agenda, designed to manage the knowledge asymmetry between the parties (e.g., Whalen & Zimmerman, 1990; Bergmann, 1992). Cromdal et al. (2008) have examined the collaborative production of initial emergency reports, showing how the operators' actions are simultaneously embedded within an interrogative protocol as well as sensitive to the unfolding dynamic of events taking place at the callers' end.

However carefully designed, institutional routines do not guarantee communicative success, and a handful of studies have examined various features of interactional trouble, offering detailed single-case analyses of incidents with fatal outcomes. For instance, Whalen, Zimmerman, and Whalen (1988) analyzed the handling of a medical emergency in which

a nurse-dispatcher insisted on speaking with the patient, in spite of having been assured by two callers that the patient was incapable of speech. This study highlights the interpretive power of the sequential environment of accounts, showing how the callers' reports of the patient's symptoms, being produced within argumentative sequences, were treated as oppositional moves and refusals to comply with the nurse's instructions, rather than as actual information on the medical status of the patient. In a similar vein, Garcia and Parmer (1999) report on a call in which the caller initially failed to communicate the severity, urgency, and proper location of a shooting incident, which prompted the operator's disbelief in the caller's telling and, eventually, led to the death of two police officers. Both studies point to the interactional basis of animosity and mistrust owing to the asymmetry of knowledge between the parties, and specifically to their difficulties in assuming what Schutz (1953/1973) termed "reciprocity of perspectives."

There are less fateful examples of interactional trouble between callers and operators. For instance, Osvaldsson, Persson-Thunqvist, and Cromdal (in press) discuss several conversational means designed to secure the parties' mutual comprehension. Such practices include displaying and ratifying candidate understandings, prompting clarification and paraphrasing, and postponing certain parts of the interrogation to a later occasion. Parker, Pomerantz, and Fehr (1995) analyze affective displays in callers' complaints, and Monzoni (2009) shows how negatively framed questions were used to deliver unveiled complaints, projecting issues of responsibility in subsequent talk. Steensig and Larsen (2008) discuss (dis)affiliative features of "you say x"-formatted questions in emergency as well as other service calls, and Eglin and Wideman (1986) unpack the notion of professional dominance by examining the sequential placement and organizational functions of interrogatives in calls to a police emergency line. Finally, Nordberg (1999) shows how confirmation of forthcoming help may serve to initiate closure of the interrogative series. As in mundane telephone calls, an important function of such pre-closing moves was to allow for a reopening of any further relevant matters or "unmentioned mentionables" (Schegloff & Sacks, 1973, p. 303).

Although work in conversation analysis has already covered some distance in explicating the key features of emergency communications across the world, several challenges lie ahead. For instance, bearing in mind that persons calling for emergency assistance often take part in or witness dramatic and potentially distressful events, there is surprisingly little work focusing on the displayed features of emotions and their bearing on the interaction between the callers and operators (but see Whalen & Zimmerman, 1998). Another central yet under-researched feature of medical emergencies concerns how patients' injuries, symptoms, and health status are established through talk. Such inquiries into emergency diagnostic interrogations would bridge over to another perennial strand of conversation analysis, namely doctor-patient interaction (see Heritage & Clayman, 2010). Finally, technological development is prompting a new generation of research (e.g., Pettersson, Randall, & Helgeson, 2004; Fele, 2008). Mobile technologies already allow persons to seek emergency assistance from an infinite range of locations and settings, and inventions such as electronic maps, mobile positioning networks, and in-vehicle emergency communication systems provide for more efficient and reliable methods of gathering incident details and organizing response activities. These recent inquiries into the socio-technical aspects of operators' call-taking and dispatch work allow us a glimpse into the future.

Conversation Analysis and Emotion and Cognition in Interaction

JONATHAN POTTER

In his very earliest published lecture Harvey Sacks (1992) gave an indication of how conversation analysts should treat cognition.

When people start to analyze social phenomena, if it looks like things occur with the sort of immediacy we find in some of these exchanges, then, if you have to make an elaborate analysis of it—that is to say, show that they did something as involved as some of the things I have proposed—then you figure that they couldn't have thought that fast. *I want to suggest that you have to forget that completely. Don't worry about how fast they're thinking. First of all, don't worry about whether they're "thinking."* Just try to come to terms with how it is that the thing comes off. Because you'll find that they can do these things. Just take any other area of natural science and see, for example, how fast molecules do things. And they don't have very good brains. (Sacks, 1992, p. 11; emphasis added)

His emphasis was on how the visibility/hearability of interaction is crucial to its operation, with "cognition" (mind, thoughts, knowledge, etc.) relevant through how it is heard and seen. In another early example, Sacks showed how speakers can display "shared knowledge" through completing another speaker's utterance—this can show the recipient that the speakers "know what's on each other's minds" (Sacks, 1992, p. 147). In this program of work cognitive or psychological analysis should be bracketed off in favor of pursuing issues of public interaction and how that unfolds.

In the half century since these arguments were first developed the outline of such a non-cognitivist approach that reworks psychological matters (including "emotional" matters) in interactional terms has become clear. By focusing on conversation analytic (CA) approaches to psychology, this entry will offer an illustrative and necessarily selective review of some of the ways psychological and emotional matters figure in interaction; it will also sketch some CA attempts to address more traditional pictures of inner processes and states; and it will briefly note the role of studies of the way psychological research identifies its objects.

Conversation Analysis as a Direct Approach to Cognition and Emotion

A central feature of the approach to interaction in CA is that speakers *display* their *understanding* through the sequential unfolding of their talk. Thus when a speaker provides an acceptance and appreciation this displays their understanding that an invitation had been issued in prior talk. Indeed, issuing any second pair part to an adjacency pair displays an understanding that the prior one was the relevant first pair part. Such an approach to understanding does not require analysts or participants to have privileged access to the cognitive or brain states of coparticipants. Understanding here is a public and practical feature of interaction. In this sense, CA is following in the tradition of philosophers such as Wittgenstein and Ryle (Coulter, 1989).

DOI: 10.1002/9781405198431.wbeal1316

Schegloff (1992) argues that such turn-by-turn patterning is the practical way in which *intersubjectivity* is sustained. Interactants monitor such organizations and use them to identify problems of understanding and initiate practices of repair. The normative and systemic organization of conversation becomes a central medium for the maintenance of intersubjectivity. In this way intersubjectivity or shared understanding is treated as a procedural issue—the turn organization of conversation provides different slots for checking and modifying understanding, each with different possibilities and constraints. Note that participants have no apparatus outside of this system for checking each other's thoughts or brain states; the unfolding and structured moments of conversation are where psychological matters become live.

A foundational issue for cognitive analysis has been the nature of knowledge and belief. This topic has been addressed in a number of strands of CA work and has become part of a recent focus on practical epistemics. Edwards (1999) argues that, for participants, the question of whether people share knowledge is a practical one, and depends on both the descriptions that embody knowledge and the conversational means through which agreement is established.

Heritage has stressed that knowledgeability is something managed in basic ways through different conversational practices; the organization of conversation lays out the “epistemic landscape” for the participants, highlighting who is more knowledgeable (K+) or who is not (K-) on relevant matters (Heritage, 2011). Thus in a series of studies of the token “oh” he shows how it is used to display a speaker's “change of state” (Heritage, 2005). For example, “oh” can “embody the experience of a recollection” and display that experience for purposes relevant to the ongoing interaction. When receiving news the token “oh” can ratify it as actually news to the recipient.

Another conversational practice that is fundamental to epistemics and therefore knowledge is that of questioning itself. The interactional-sequential logic of questions is that those issuing the question propose themselves as uninformed on some matter and at the same time project the recipient as informed. Note that in social situations where questions do not mark a lowly position in the epistemic landscape (in classroom teaching or news interviews) “oh” tokens are much less common. Questions can be designed to offer a candidate answer (Pomerantz, 1988) or embody polar options to grammatically constrain response possibilities (Raymond, 2003). Each of these designs can establish a different epistemic relation, a different level of K+ and K-, between speaker and recipient.

Epistemic relations can be finessed in a range of different ways using tag questions. They can index lowered epistemic status (K-) in the way that was highlighted by early work in sociolinguistics (Lakoff, 1975). By being asked for confirmation for a declarative, the other is treated as in a position (K+) from which they can ratify it. However, tag questions can also be used to mobilize support for an assertion where the speakers present themselves in an authoritative (K+) position (Hepburn & Potter, 2011).

Another major area of psychology which interactional work contributes to would traditionally be glossed as attitudes, attitude change, and social influence. CA contrasts with these psychological approaches by focusing not on underlying, enduring attitudes, but on the conversational practices of expressing an assessment of something and how such assessments unfold interactionally. Pomerantz's (1984) work shows that there is a very strong normative expectation with the issuing of an assessment for the recipient to issue an assessment of their own. Such second assessments have a preference organization: the preferred second assessment follows directly, is upgraded, and is often simple; the dispreferred second assessment comes after delay, the disagreeing component often comes late in the turn, and it is often downgraded.

The nature of an assessment is a complex topic. Sometimes it will involve explicit use of moral or evaluative terms (*good, great, poor*) but at other times assessment will be built using

descriptions. Assessments can be built as “object side” or “subjective side” (*that coffee is nice, I love that coffee*; Wiggins & Potter, 2003), and where topics are delicate, assessments can be built as entirely separate from the wishes or values of the speaker (Edwards, 2007).

CA offers a treatment of all these features of “cognition” that starts with the public and practical, and how psychology can work as something intelligible and relevant in interaction. The treatment of emotion has been less developed but starts with the same focus on the public and practical. Rather than looking at psychological and physiological disturbances within the individual, attention is focused on practices and in particular the sequential and interactional role of various features of prosody and timing. Couper-Kuhlen (2009) suggests that a CA approach to emotion will focus on displays (thereby bracketing off questions of mental and physiological states) and treat those displays as realized through embodied practices, which are situated in sequential positions, and interpreted in a context-sensitive fashion (p. 95). This contrasts strongly with traditional psychological work on emotion where the primary data source is aggregated questionnaire responses about, say, when the participant has cried in the past and how they felt about the crying. In that work emotion is often treated as something hard to directly measure except via physiological means.

Hepburn (2004) studied crying in calls to a child protection help line. She identified a range of features that in different combinations are treated as signs of upset. These include talk that is unusually quiet; is delivered with a tremulous voice; is delivered with very high pitch; contains excessive aspiration; is accompanied by, and delayed by, wet or snorty sniffs; is unusually or erratically delayed; and is accompanied by full-blown sobs. Crying is often combined with extrematized descriptions of negative feelings and with apologies.

Analysis of receipts to crying in the same collection of calls suggests that they commonly include *take-your-times*, which orient to and license the disruption caused to the ongoing interaction; sympathetic receipts (*oh gosh, tut* particles); and empathic receipts (Hepburn & Potter, 2007). Empathic receipts are particularly interesting, as the classic picture of empathy involves a cognitivist image of accurate understanding of the recipient’s feelings. Analysis of such receipts, however, highlights two features. First, they contain a formulation of the other’s psychological state that draws on information delivered just prior, in terms of either the severity of the emotional display or explicit self-ascriptions. Second, they mark this formulation as epistemically contingent on the information given. There is a strong orientation to the recipient having primary rights to their own mental state.

Couper-Kuhlen (2012) has highlighted some of the patterning of “affective displays” such as disappointment and the reception of complaints. She has highlighted how the understanding of affect displays is strongly sequentially located and associated with broad prosodic patterns such as “subdued” or “dynamic.” She concludes that voice “in displaying affective stance is not a spontaneous expression of some inner state but rather a carefully deployed and manipulated resource, used in complex interaction with verbal and other non-verbal resources.”

Conversation Analysis’s Implications for Classic Cognitive Psychology

For some workers in the more ethnomethodological tradition, the engagement with classic cognitive psychology involves taking on too many of the conceptual confusions of cognitivism, and should thus be avoided (Coulter, 2005). For some discursive psychologists exploring the broader implications of CA for cognitive research can be valuable, but should avoid assuming cognitivist pictures of human action.

Hopper (2005) considers the idea that conduct may be strategically planned and guided by such plans. He worked with a corpus of phone calls made to US President Johnson’s

office soon after he became president. These calls were very similar: They typically involved thanking supporters and accepting congratulations. Hopper suggests they provide a natural setting for the consideration of the operation of strategic thinking, for example by using the calls as an environment to initiate the cost-cutting agenda that would characterize Johnson's presidency. However, Hopper concludes both that it is hard to find convincing evidence of strategy at work, and that even if such strategies were operating they would need to be flexible enough to work with the varied contingencies of talk.

Schegloff (2006) has taken a different approach. Rather than follow the route of attempting to use human conduct as a pathway to cognitive entities, he has tried to highlight the consequences of basic CA findings for classic forms of cognitive analysis. In effect, the findings of CA describe a highly complex system of interaction that includes regular phenomena that set a profound challenge for classic psychological models to account for. These include phenomena of turn and sequence organization, repair, a wide range of projection phenomena, and person reference. Schegloff highlights the kinds of competence that any interactant must have to fully take part in conversation and in particular how that competence must deal with the different *possible* trajectories of conduct that arise in the contingency of actual talk. Speakers must be capable of designing their talk and other conduct so that it can be "taken up for the 'possible Xs' that compose it," and they must attend to:

the talk and other conduct produced by a co-interactant so as to 1) address the multiple "possible Xs" that compose it, 2) resolve that multiplicity of possibilities and arrive at some determinate grasp of what the other was saying/doing, and 3) display that grasp in their own responsive conduct—sometimes correctly, sometimes not, (Schegloff, 2006, p. 146)

With this approach Schegloff is leaving the work of addressing any cognitive implications of these phenomena with cognitive researchers; his aim, though, is to highlight just how complex the conduct is that they need to model.

Note that what Schegloff and other CA workers are doing here is not attempting to make a contribution to cognitive psychology or a broader discipline of cognitive science. Rather they are laying out how "psychological matters" are live for participants in interaction and in particular the way they are organized sequentially and structurally. The point is that a cognitive science or cognitive psychological approach might need to consider the implications of this for their assumptions, theories, claims, and empirical methods. For example, neuroscientific work on "emotion" or "empathy" might need to consider the sorts of public and interactional matters that become live when upset is displayed and the sorts of sequential and normative environment in which such matters unfold, as well as recognize the timescale on which participants are able to apprehend and produce actions (Hepburn, 2004).

Conversation Analysis and Psychological Method

CA has important implications for the analysis of cognition and emotion through the light it has thrown on psychological methods as interactional occasions. Psychological research identifies the nature of its phenomena through instruments such as tests, experiments, survey interviews, focus groups, and so on. Such procedures involve forms of institutional talk, and the implications of this for findings can be important.

Antaki and colleagues have conducted a series of studies of psychological assessments and systematic survey interviews (Antaki & Rapley, 1996; Antaki, 2006). Crucially, this

work shows some of the ways in which the findings can be influenced by standard conversational processes. Although it was not his main object, Schegloff (1999) studied a test for “pragmatic deficit” consequent on brain surgery, and noted an interesting tension between the conclusions of the test for the way the recipient’s competence was understood and what he demonstrated in his sophisticated orientation to the demands of the testing situation itself.

Conclusions

CA was not designed as an approach that would address psychological questions as classically formulated. Indeed, Sacks emphasized that it would be a different order of research. One of the basic things that is involved when learning the analytic procedures of CA is to move away from interpreting talk as a consequence of underlying desires, intentions, and feelings. However, as CA has developed it can be understood as an approach which provides an illuminating, systematic, and progressive account of a wide range of human conduct. Indeed it provides a foundational method and body of findings for a discursive approach to psychology (Edwards & Potter, 2005). CA has presented a precise and comprehensive challenge to classic approaches to cognitive psychology which, as yet, has yet to be met with the sophistication required. Important work will continue on the interactional organization of psychological research methods.

Conversation Analysis and Ethnomethodology

PAUL TEN HAVE

There can be hardly any doubt that ethnomethodology has been a major influence in the emergence of conversation analysis (CA) as a unique perspective in the human sciences. Gradually, however, the two seem to have drifted apart. The current situation is ambiguous: For some of its practitioners, CA is still part of the ethnomethodological movement, while many others treat it as an independent pursuit. This entry will provide a summary characterization of ethnomethodology with a focus on its research practices and a consideration of its relation to CA.

Harold Garfinkel

Around 1960 Harold Garfinkel (1967) developed a specific approach to the core problem of sociology: "How is social order possible?" He maintained that the orderly aspects of social life are the product of the continuous application by members of society of what he called "ethno methods," ways of doing that make the sense of what they are doing observable and inferable. It should be noted that these "methods" are not considered to be standardized; they are mostly informally adapted to the circumstances in which members live their lives. The concept that is most often used to focus on such a situational contingency is "indexicality." "Indexical expressions" are statements whose sense depends on the circumstances in which they are uttered. As Garfinkel writes: "I use the term 'ethnomethodology' to refer to the investigation of the rational properties of indexical expressions and other practical actions as contingent ongoing accomplishments of organized artful practices of everyday life" (Garfinkel, 1967, p. 11). Note that his interest is not in the distinction between indexical and non-indexical expressions as such, which is a philosopher's problem, but in indexicality as an unavoidably present phenomenon of practical actions and expressions.

Because "ethno methods" are such an integral part of everyday life, they are in fact unremarkable, and hence hard to study. Therefore Garfinkel in his early work (1967, pp. 35–75) used specific procedures to make these methods "observable." In his "breaching experiments," he created situations in which some taken-for-granted "background expectancies" were not applicable, or he asked his students to do so. In one of these experiments, for instance, students had to act in their parents' homes as if they were boarders. Two kinds of reactions were observable in this and other "experiments": On the one hand people were surprised, shocked, and angry, and on the other hand they sought to "normalize" the situation by finding some explanation for it.

Although these early experiments were useful as demonstrations of the existence and significance of the phenomena of interest, they cannot be properly seen as serious studies. In other empirical contributions, Garfinkel used more ethnographic approaches, but he did prefer to study situations in which "normality" was somehow at issue, for instance by studying the ways in which a transsexual person had to demonstrate her femininity (1967, pp. 116–85).

DOI: 10.1002/9781405198431.wbeal1337

Taking a historical perspective, it can be said that Garfinkel's initiative had its roots in two separate theoretical traditions. On the one hand, he did his graduate studies at Harvard under the supervision of Talcott Parsons, who developed a very abstract theoretical schema of social action as a kind of precondition for any empirical study of society. But on the other, Garfinkel criticized this approach on the basis of insights from the phenomenological philosophy of writers like Alfred Schutz, Aron Gurwitsch, and Edmund Husserl. Central to this critique was that people like Parsons tend to treat the members of society as what Garfinkel calls, somewhat ironically, "judgmental dopes" (1967, pp. 67–8), as if they are blindly enacting what a sociological or other theory expects them to do. For Garfinkel members of society actively create and maintain social order, and the ways in which they do so can be studied, which is the task that ethnomethodology has set for itself.

Ethnomethodological Studies

After Garfinkel's early demonstrations, his students had to find their own ways in which they could study "ethno methods." In the early days, this was mostly done using a range of ethnographic approaches. Lawrence Wieder, for instance did a study of a "half-way house," a rehabilitation center for convicted drugs users (1974). He focused on the ways in which both staff and inmates accounted for the latter's lack of participation in the program by referring to a kind of solidarity code. Instead of using this "code" as an explanatory "folk sociology" to be systematized, Wieder studied, in detail, *how* the "code" was actually used in various everyday situations, as an accounting practice.

After 1970 Garfinkel stimulated his graduate students, such as Kenneth Liberman, Eric Livingston, and Michael Lynch, to do what he called "ethnomethodological studies of work," in which attention was to be paid to the everyday details of very specialized activities. The idea was that such activities, as in scientific research, ultimately depend on concrete, local practices which are, however, ignored in any account of those activities (see Garfinkel, Lynch, & Livingston, 1981). In order to be able to understand what is going on in a scientific laboratory, one has to have a basic knowledge of the sense of what is going on there. Garfinkel has called this being "vulgarly competent" in the activities in the setting (Garfinkel & Wieder, 1992). The acquisition of such a competence is, therefore, a basic requirement for doing an ethnomethodological study.

In their *An Invitation to Ethnomethodology* David Francis and Stephen Hester (2004) offer a kind of general procedure for doing ethnomethodological research. They stress that the point always is how to gain *access* to the procedural foundations of the activities of interest, their "observability" and "accountability." This requires the transformation of everyday sense-making practices from resources *of* analysis into topics *for* analysis. For these authors, "doing ethnomethodology involves taking three methodological steps":

1. Notice something that is observably-the-case about some talk, activity or setting.
2. Pose the question "How is it that this observable feature has been produced such that it is recognizable for what it is?"
3. Consider, analyse and describe the methods used in the production and recognition of the observable feature. (Francis & Hester, 2004, p. 26)

Francis and Hester explicate three different "modes" of this "three-step method of ethnomethodology": "self-reflection," "analysis of recorded talk and action," and what they call "acquired immersion." The common basis of these modes is "the presumption that analysis is premised upon immersion in the activity under study" (p. 26). In other words, in order to analyze an activity, one has to understand it *as* a participant in such an activity.

In the first of these modes, “self-reflection,” the ethnomethodologist’s own understandings and activities provide the phenomena for analysis. Sudnow’s study of his own piano playing (1978) is an obvious example of this mode. In the second mode, “analysis of recorded talk and action,” ethnomethodologists rely again on their own competencies, this time specifically as conversationists and speakers of natural language. This is, of course, the preferred mode of CA, which can also be described as using the three steps outlined above. When the analyst is not able to rely on his or her competencies, the third mode, “acquired immersion,” becomes relevant. This involves getting enough membership knowledge in a particular setting to understand as from inside the specialized activities that constitute that setting. This is what Kenneth Liberman did for his study of practices of formal reasoning in the philosophical discussion of Tibetan monks (2004).

Francis and Hester note that their three modes “are not mutually exclusive, nor are they unrelated.” Instead, “they can usefully be combined. Indeed, the separation of them into distinct modes is somewhat arbitrary” (2004, p. 27). Indeed many recent ethnomethodological studies do in fact use at least two of these three modes, most often recordings and acquired immersion, as Liberman did. Other examples are available in a recent collection of papers edited by Hester and Francis (2007).

It should always be remembered that ethnomethodology emerged as a critical reflection on the basic theories and methods of sociology. This has led, on the one hand, to empirical studies like the ones mentioned above, and on the other to a series of programmatic, theoretical, and philosophical publications by Garfinkel himself and others such as Graham Button, Jeff Coulter, and Wes Sharrock, who often demonstrate the affinity of ethnomethodology with Wittgenstein’s later philosophy (see Suggested Readings). The core point of these contributions is that ethnomethodology “re-specifies” the basic conceptual foundations of sociology and the other human sciences as investigatable properties of members’ situated activities. Ethnomethodology, then, is offered as an *alternate* sociology (Garfinkel & Wieder, 1992).

Ethnomethodology and Conversation Analysis

As noted in the introduction, opinions among researchers in CA regarding its relation to ethnomethodology vary from seeing CA as one way of doing ethnomethodological studies to seeing it as an independent pursuit. Garfinkel’s initiative was clearly a major influence in the development of the CA approach by Sacks and Schegloff. But it is also clear that ethnomethodology and CA have drifted apart in various ways. In this section, the focus will be on aspects of the research methods used in CA against a background of ethnomethodological considerations (see ten Have, 2004, 2007, pp. 43–50).

A major feature of ethnomethodology is that it struggles with what can be called “the problem of generalities” (ten Have, 2004, pp. 174–6). From the first quotation from Garfinkel given above, it should be clear that for him the interest is in the local production of actions in their uniqueness, and in so far as these actions have general features, these generalities are produced locally, as single achievements. Now take a look at an early statement by Sacks.

The gross aim of the work I am doing is to see how finely the details of actual, naturally occurring conversation can be subjected to analysis that will yield the technology of conversation.

The idea is to take singular sequences of conversation and tear them apart in such a way as to find rules, techniques, procedures, methods, maxims (a collection of terms that more or less relate to each other and that I use somewhat interchangeably) that can be used to generate the orderly features we find in the conversations we examine. The point

is, then, to come back to the singular things we observe in a singular sequence, with *some rules that handle those singular features, and also, necessarily, handle lots of other events.* (Sacks, 1984, p. 411; emphasis added)

In a simplifying manner one can say that, for Sacks, the analysis of conversational phenomena is done in two steps: First one analyzes a single case, then one formulates "rules" which can and will be applied to other instances. The first step is an ethnomethodological one; the second goes beyond that. It is the second step that has often been criticized by hard-core ethnomethodologists. In various publications, Michael Lynch has expressed his misgivings about CA's aspirations to be a "science." For instance, in the "methodological appendix" to their book on the Iran–Contra hearings, Lynch and Bogen (1996, pp. 269–70) refer to Wittgenstein's complaint about the prevailing "craving for generality" in the philosophy of his day, and the concomitant "contemptuous attitude towards the particular case." And they add: "For Wittgenstein, descriptions of singular activities are valuable precisely because they cast into relief diverse, unexpected, yet intelligible organizations of language use." On the other hand, Lynch has elsewhere expressed his appreciation of the "first step" of the CA procedure as "the ethnomethodological foundations of conversation analysis" (2000).

Emanuel Schegloff has confirmed CA's indebtedness to ethnomethodology on this point: "Although there is much which differentiates CA from many central features of ethnomethodology . . . , the local determination of action and understanding has ethnomethodology as its most substantial and proximate source" (Schegloff, Ochs, & Thompson, 1996, p. 15). In other words, a major lesson of ethnomethodology for CA is to take the first step in the analysis seriously; that is, not to perform it as a simple act of "coding," which, of course, has consequences for using a quantitative research design in CA studies (Schegloff, 1993; Heritage, 1999).

CA itself is currently being practiced in a variety of ways, some closer to ethnomethodology than others. In his studies of telling good or bad news, Douglas Maynard (2003), for instance, places his careful CA analyses of a wide range of instances of such tellings in an ethnomethodological framework by suggesting that they constitute a sort of "breaching" event (see pp. 1–33, specifically p. 6). Most "workplace studies" use a CA-based analysis of recorded interactions against a background of an ethnomethodologically inspired ethnography (e.g., Heath & Luff, 2000; Nevile, 2004). In contrast, one can note that most CA work in the "interaction and grammar" tradition hardly refers to ethnomethodology.

CA, then, can be seen as ethnomethodology's younger sister, who has gone her own, partly independent, but highly successful way. While ethnomethodology offers a broad *alternate* philosophical and empirical perspective for the human sciences, CA presents a more limited, but extremely productive, conceptual and empirical approach for studying the core activity of human society: embodied verbal interaction.

Conversation Analysis and Gender and Sexuality

CELIA KITZINGER

Gender and sexuality are routinely displayed, negotiated, and constructed through talk-in-interaction. The cumulative, empirically derived body of knowledge foundational to conversation analysis (CA) as a discipline is increasingly used in feminist (and other politically engaged) research as a way of engaging with gender and sexuality as part of the politics of everyday life.

The earliest feminist work drawing on CA was Zimmerman and West's (1975) exploration of interruptions in cross-sex conversation and then Goodwin's (1990) analyses of girls' talk. Since the early 2000s there has been a dramatic increase in CA and CA-influenced research dealing with topics such as refusing sex (Kitzinger & Frith, 1999), transgender issues (Speer & Green, 2007), "coming out" as lesbian or gay (Kitzinger, 2000; Land & Kitzinger, 2005), violence against women (Stokoe, 2010), heteronormativity (Kitzinger, 2005a, 2005b), childbirth helplines (Shaw & Kitzinger, 2007; Kitzinger, 2011), and gender categories in interaction (Stokoe, 2010; Speer, 2005; Kitzinger, 2007). Feminist researchers have found that CA offers a powerful and rigorous approach for exposing mundane, routine, everyday forms of oppression—the "micro-inequalities" of social life. CA is also increasingly used in applied settings as part of training and evaluation of woman-centered services (Kitzinger, 2011).

The emergence of "feminist CA" has been criticized both by feminists and by conversation analysts. It is sometimes proposed that CA has too narrow and restrictive a scope and that its attention to the fine details of talk, independent of speaker characteristics (such as gender), render it unsuitable for understanding how power and oppression operate in relation to gender and sexuality (see Kitzinger, 2000, for overview). Others have dismissed CA as jargon-ridden, impenetrable, and—despite its stated focus on participants' orientations—divorced from speakers' own understandings of what is happening in social interactions. It has also been claimed that feminist CA so violates basic methodological principles as to cast doubt on whether it is genuinely identifiable as CA/ethnomethodology (see response in Kitzinger, 2008a). Most recently, however, theoretical critique has been overridden by the best possible evidence of the value of CA for studying gender and sexuality, that is, by the development of a substantial body of empirically based feminist CA (e.g. Speer & Stokoe, 2010) that draws on the key findings of the discipline across the generic organizations for conversation, namely turn taking, sequence organization, repair, word selection, and overall structural organization.

Since the 1970s, when both CA and feminist research on language were in their infancy, the two fields have developed and intersected in important ways. This intersection can be illustrated with reference to just one of the key generic organizations identified by CA: how turn taking is managed by participants in talk-in-interaction. Early feminist work relating gender to the turn-taking model suggested the existence of gender differences: for example, that male speakers disproportionately interrupt women's talk (Zimmerman & West, 1975), or that the turn-taking model is gender-specific to males, since women regularly speak in cooperative overlap (Coates, 1997). Neither claim about sex differences has been

2 CONVERSATION ANALYSIS AND GENDER AND SEXUALITY

borne out by subsequent work (Kitzinger, 2008b). Instead, developments in CA understandings of turn taking have offered the opportunity for more sophisticated analyses that show how the turn-taking system is negotiated by speakers who are analyzably managing issues relating to gender or sexuality in their talk. The following two data analyses offer a glimpse of the value of the turn-taking model in addressing gender/sexuality issues in talk-in-interaction.

In excerpt (1), one student, Linda, is launching a disagreement with another about how one might feel on learning that someone for whom one felt romantic interest was intersex. In the course of her turn she “comes out” as someone who has felt sexually attracted to another woman. I have displayed part of the talk in bold as a device for drawing the reader’s attention to the fact that Linda’s information about her own past romantic attractions is embedded part way through an if/then formulation (a compound turn construction unit [TCU], Lerner, 1996), the first component of which (*If you’ve thought of yourself as heterosexual and you suddenly find yourself attracted to a woman*) projects some final component (which turns out to be *it’s very disturbing*)—and only after production of this final component has the TCU been brought to possible completion.

(1)

- 01 LIN: it does.
02 LIN: it does have an effect on you because
03 (0.2) **if you’ve thought of yourself as heterosexual**
04 **(1.0) and you (.) >suddenly find yourself attracted**
05 **to a woman** °it happened to me,< (0.2) a few years ago°
06 it’s very (0.8) disturbing.
07 CK: [mm]
08 LIN: [in a] way it’s it’s (0.2) makes you very anxious
09 (.)
10 LIN: because you then don’t know how you’re supposed to respond

Co-conversationlists’ shared orientation to compound TCUs means that speakers can insert additional material between the “if” and the “then” components of their talk with reasonable assurance that (since speaker transition is not yet relevant), this material will not be topicalized or treated as other than parenthetical to the otherwise ongoing business of the talk. Information embedded inside a compound TCU is protected from being topicalized (e.g. “what did you do?”), assessed (e.g. “that must have been weird”), or treated as offering the opportunity for a second telling (e.g. “oh that happened to me too”). Here, then, the speaker is actively using the grammatical structure of language (in conjunction with practices of turn taking and sequence organization) as a resource for the social action of “coming out” discreetly (see Kitzinger, 2000, for a full analysis).

Excerpt (2) is drawn from a call to a birth crisis helpline, and the caller, Hannah, is describing what happened after her emergency hysterectomy. She is cautiously building a case for the possibility that her health-care team may be to blame for her hysterectomy—a claim that she treats as possibly overstepping the limits of propriety (e.g. as unsubstantiated, hysterical, or paranoid). On the very brink of producing this somewhat delicate accusation, she slows down her talk mid-TCU (with the silence after *were* and the increasingly protracted sound stretches), thereby creating an opportunity for the call-taker (“CLT”) to come in prior to completion and to complete the TCU on her behalf (Lerner, 1996).

(2) [BCC 205]

01 HAN: if things had just naturally gone wro:ng
 02 .hh[hh] they'd've been looking at the file=
 03 CLT: [mm]
 04 HAN: ='n: sayin' oh this woman was just damned
 05 unlucky[:.]
 06 CLT: [ye]ah. hh
 07 HAN: uhm (0.2) but I almost felt that these::
 08 (1.0) looking ba:ck: (0.2) that (.) **these**
 09 **people we:re (.) coming i::n to::**
 10 CLT: **cover their ba:ck[s.]**
 11 HAN: [c]over themse:lves.
 12 in [some] wa:y.
 13 CLT: [yes:]
 14 CLT: .hhh y- yours is a very: intelligent and
 15 reasonable response to all this:.

In this marked departure from ordinary turn-taking procedures, anticipatory completion of a coparticipant's TCU renders the completed turn a coproduction, jointly constructed across the talk of the two participants (Lerner, 2002). In this instance, the call-taker is able to demonstrate an empathetic understanding of the sort of thing that Hannah would treat as an adequate completion in part because Hannah has supplied an implied contrast between what would have happened if *things had just naturally gone wrong* (line 1) and what may instead—with the contrastive *but* (line 7)—have been the case. By voicing the (unspoken, delayed) part of Hannah's turn, the call-taker is engaged in an affiliative action, showing both that she understands Hannah's position, and—by co-implicating herself in its articulation—that she is treating it as a reasonable position to take. Hannah's subsequent delayed completion of her own talk with a near-repeat of what the call-taker has said (line 11) endorses the call-taker's completion while also reasserting authority over her turn's talk and making relevant a next turn responsive to it. This next turn receipts Hannah's claim and positively assesses it (lines 13–15). Displays of empathetic understanding are an important component of help-line work in “woman-to-woman” organizations such as the birth crisis line, and the turn-taking model offers insights into how these are accomplished, which can be harnessed for training (Kitzinger, 2011).

These two examples illustrate applications of the turn-taking model to feminist concerns. They were specifically selected as such since turn taking has sometimes been singled out for criticism by those who consider CA unsuited to feminist ends (see Kitzinger, 2000). Equally, however, all the other generic organizations of conversation are also realized in and through the particulars of any given interaction—and these too can be oriented to issues of gender/sexuality or related feminist concerns. So, for example, sequence organization is integral to all CA data analysis (because it is integral to all talk-in-interaction). Feminists have shown that young women's self-reports of how they refuse sex (using appreciations, mitigations, and accounts) bear little relationship to the idealized representations of “just say no” in assertiveness training and date-rape prevention training manuals, but they do rather closely mirror CA findings about how dispreferred responses are normatively done (Kitzinger & Frith, 1999). Another key generic organization of conversation, word selection, has been heavily researched by feminists exploring the uses of gendered terms such as *woman*, *lady*, *slut*, *bloke* (e.g. Kitzinger, 2007; contributions in Speer & Stokoe, 2010; Stokoe, 2010). These different domains of generic organization are pervasively intertwined—as, for example, when a study showing how heteronormativity is displayed

in interaction finds that the sequentially relevant next action is designed differently depending on whether the word selected in the initiating turn is *wife* or some nonfamily reference term (Kitzinger, 2005b).

Research using CA to study gender/sexuality issues is still relatively new and underdeveloped. It is clear, however, that CA offers a rigorous method for the analysis of actual recorded human interaction (rather than second-hand reports of it) with a commitment to understanding participants' own orientations and actions. It is in the course of these ordinary human interactions that, for example, "comings out" are accomplished, woman-to-woman empathy displayed (or withheld), sexual refusals expressed (and accepted or not), and heteronormative assumptions made apparent. These are the actions out of which genders and sexualities are constituted in everyday life.

Conversation Analysis and Identity in Interaction

CHARLES ANTAKI

The perspective of conversation analysis (CA) on identities can be described as social constructionist and non-essentialist. It declines to take it that the person *has* this or that given identity and prefers to watch as the person moves in and out of the multiple categories that society offers. That movement, CA continues, is entirely contingent on the demands of the moment, and, subject as it must be to complex social forces, is nevertheless routinely mediated by talk.

Since Harvey Sacks's foundational work on what he called "membership categories" (see Sacks's early lectures in 1966, reproduced in Sacks, 1992, vol. 1), CA has worked to the proposition that, as a pair of later commentators put it: "Membership of a category is ascribed (and rejected), avowed (and disavowed), displayed (and ignored) in local places and at certain times, and it does these things as part of the interactional work that constitutes people's lives" (Antaki & Widdicombe, 1998, p. 2). CA does not tell us what catalog society will offer its members as identity categories at any one moment, or why that catalog exists and not some other (it cedes that task to ethnography, anthropology, and sociology) but it is articulate about how those identity categories are conjured up, and what work they do.

In its methods, CA shares important principles with many other kinds of discourse analysis of identity (for a broad view see Benwell & Stokoe, 2006). It takes it that identities appear in talk or text that is naturally found (in the sense of not invented or imagined by the researcher); that words which signify or imply identities are to be understood in their co-text; that the analyst is to be sensitive to the words' nonliteral meaning or force; and that the analyst is to reveal the consequences achieved by the identities conjured by the words' use—as enjoyed by those responsible for the words, and suffered by their addressees, or the world at large.

What is unique about CA is that it adds two further requirements on those who research in its name. One is that data must be approached without a priori ideas as to what identities are in play in the given scene—the identities must be made visible among the participants, and the analyst's own interpretation is disqualified. The other specialist CA injunction is that identity matters be understood by analyzing the words in their developing, interactional sequence: Words in talk take their force from the particular moment and manner of their delivery, and to strip them from their natural environment is to put them in a cage and watch them wither.

For a person to "have an identity," then, is to be cast—at least momentarily—into a recognizable social category with associated characteristics or features, with interactional consequences. That casting need not be explicit. There is no need to call someone a mother for her to be treated as one—and, the CA argument goes, effectively in that scene to *be* one. The casting can be done as well, and more economically, by talking about her in ways that only make sense if one's hearers infer that she is indeed a mother. The same person a minute later will pick up a phone and be treated as the office-worker she (also) is; later in the day she will be—will be referred to as, treated as, and talked to as—a neighbor, a daughter, and a stranger in consecutive episodes of interaction. The next day, at the airport,

2 CONVERSATION ANALYSIS AND IDENTITY IN INTERACTION

institutional forces will combine to judge whether she is an American, a smuggler, or a terrorist; and so on, for an endless series of daily encounters.

The force of “having an identity” is its consequentiality in the interaction—what it allows, prompts, or discourages participants to do next. Here is a pair of snippets, showing one kind of consequentiality of an identity ascription:

- (1) [Zimmerman (1998, p. 100). “CAT” is the call-taker at an emergency services call centre, “CAL” is the caller.]

01 CAT: Mid-City emergency
02 CAL: → .hh tch hi: we got u:h (.) this is security at thuh
03 bus depot. Greyhound bus depot?=
04 CAT: =yes ma'am=
05 CAL: =an' we got a guy down here that's uh:
06 (0.6) ((background noise))
07 over intoxicated hhh .hh he just- he's passed out.

In the self-ascription at lines 2–3, the caller's identification as *security at thuh bus depot* is fitted to the institutional preferences of the emergency services call center: that callers declare themselves—as soon as possible—to be competent witnesses to emergencies, and as qualified as possible as solicitors of help. As a member of the security team at a recognizable public facility, the caller smooths the path of the telephone call. Compare the turbulence when such an identification is missing:

- (2) [Zimmerman (1998, p. 100)]

01 CAT: Mid-City emergency
02 CAL: yes sir uh go' uh couple gu:ys over here ma:n
03 they thin' they bunch u wi:se ((background
04 noise))=
05 CAT: → =are they in yur house? or is this uh business?

Denied the caller's identification, the call-taker has to rectify the resulting informational absence: They ask whether this is a domestic matter, or a public one, as the two events may have different contingencies in how the service is to respond. The point to labor is that identifications—of oneself, a copresent other, or a third party—are functional things; they do some interactional work. In the emergency call, the caller's identification helps warrant their request for help; in the infinitely many other interactions a person will have in their daily routines, there will be an infinite variety of other actions that the identification will perform.

Here is another example, from Edwards's work on talk in marital counseling (Edwards, 1998). “Connie” is telling the counselor about the infidelities of her partner, “Jimmy.” How to refer to Jimmy's other lover? Is she a woman, or, as Connie puts it, a *girl*?

- (3) [Edwards (1998, p. 25), renumbered]

01 CON: I can't accept (1.0) I can't accept (1.0) y'know: (.)
02 what he's telling me, (0.5) y'know?=I just belie:ve
03 → that this girl was here all alo:ng

As Edwards puts it, “the expression ‘this girl’ serves to downgrade her status, if not her threat, as an unattached, unmarried, available, possibly young, female”—all without doing so explicitly and making Connie seem aggressively prejudiced. But does *girl* always imply sexual status? Hardly; all descriptions are indexical, and to prove the point here is Connie

again, this time mobilizing the word *girl* in a context which gives it an entirely different meaning:

(4) [Edwards (1998, p. 27), renumbered]

01 CON: >What I would like to be able to do is,< when my friend
 02 rings me up, (0.5) every six weeks, or: when they're
 03 → having a ↑girls' night out, >to be able to say,< (.)
 04 "yeh, I'd love to go".

A *girls' night out* is, as Edwards points out, a common English expression for a one-off, informal, female-only excursion where the emphasis will be on companionship. Indeed Connie later adds *when I go out with the girls, it's all married women talking about our kids or something, or somebody rings .hh they have a problem . . . that's the girls' night out*. For Connie, the *girls* provide an occasion to share, commiserate, and show public, non-sexual solidarity—at the opposite pole to Jimmy's *girl*, who provides an illicit sexual escapade.

Such concentration on identity categories and the work they do is traceable back to the work of one of CA's founders, Harvey Sacks. In its wider form, open to sequential analysis and a discursive reading, it informs work such as Edwards's, described above. In its narrower form it is sometimes known as *membership categorization analysis* (MCA). An example from the work of Sacks himself illustrates the idea. Here is an extract from a newspaper account of an interview with a US fighter pilot:

I certainly don't like the idea that I might be killing anybody . . . [b]ut I don't lose any sleep over it. You have to be impersonal in this business. Over North Vietnam I condition myself to think that I'm a military man being shot at by another military man like myself. (quoted in Sacks, 1992, vol. 1, p. 205)

As Sacks observes, any description of events is a choice which disqualifies others, and renders certain inferences more salient in the reader's mind. Here, the pilot's identification of both himself and those against whom he is fighting as military men "delocalises the affiliations of the personnel," as Sacks puts it (1992, vol. 1, p. 206); "what is relevant . . . is not that we are the military of the US and they of Vietnam, but that we are both military"; and indeed both simply doing the job, as it were, that the category "military man" entails. The pilot may well not like the idea that he is killing anybody, and his re-identification as (merely) a military man distances his actions from too close a personal matter of choice. A phrase like "military man" is a sort of binding agent—what Sacks calls a "Membership Categorisation Device"—that brings together disparate objects (this individual US citizen, that particular, if anonymous, Vietnamese man) into a coherent set with given interdependencies. Even the most banal of descriptions will conjure into being a very specific connection between two objects: thus the child's story that includes the phrases "The baby cried. The mommy picked it up." immediately specifies—without effort—that the baby is this mommy's baby, and that she picked it up to do with it what mommies do with crying babies (Sacks, 1992, vol. 1, p. 236).

MCA takes this kind of insight, and Sacks's speculations about various kinds of pragmatic rules that bind together category names and their associated behaviors and other predicates, and builds a highly articulated apparatus with which to analyze texts and talk (see, for example, the programmatic account in Lepper, 2000). The more taxonomic style of some MCA work has not been popular among most CA researchers, who prefer to attend to their normal interests in charting the flow of talk, and describe the play of identity categories in interaction without the complex vocabulary of MCA. Hester and Eglin's edited volume (1997), however, offers examples of MCA work which tries to find a way of combining MCA with sequential analysis.

Research using general CA principles of sequential analysis has thrown light on three kinds of identity category, to use the useful tripartite division suggested by Zimmerman (1998): “transportable,” “situational,” and “discourse” identities. The first are what would be thought of as traditional sociological categories, such as gender (e.g. Speer & Stokoe, 2010); disability (e.g. Rapley, 2004), or age (e.g. Nikander, 2002); the person can “transport” such a membership from one scene to another. Perhaps the most obvious (and well-researched) such “transportable” identities in talk are those which are signaled by languages, dialects, and codes (see, for example, chapters in the collection by Auer & Li Wei, 2007). The second includes such occasioned identities as language student (Hauser, 2005) or call-show host (Hutchby, 1996), which are bounded by a given scene and setting. The third kind are categories which emerge from the discursive demands of the communicative exchange—for example, one could inhabit the identity of a “troubles-teller” (Jefferson & Lee, 1981) or an “authorised troubles-recipient” (Antaki & Horowitz, 2000). More to the point, the research has shown how these identities emerge in interaction, and are used for interactional ends.

In sum: CA is the study of social action as it is brought about through the design, delivery, and uptake of language in interaction. To adapt J. L. Austin’s happy phrase, people do even large-scale things with the slightest of words; and one of the large-scale things people do is impose *identities* on themselves and others. CA’s contribution to the social science of identity is to show how talk brings identities into being in the here-and-now of interaction, and how those identities are consequential there-and-then.

Conversation Analysis and Institutional Interaction

LORENZA MONDADA

Within the last fifty years, the study of institutional interaction has been carried out by a large number of scholars referring in diversified ways to conversation analysis (CA), ethnomethodology (EM) and workplace studies (WPS). This entry presents the specific approaches of these three related fields, elaborating on their major topics. In the conclusion, their theoretical, methodological, and applied contributions are highlighted.

Talk at Work and Institutional Talk-in-Interaction

As CA emerged during the 1960s, and consolidated during the 1970s, one of its main objectives was the study of conversational “machinery” based on turn taking and sequence organization, for example adjacency pair, repair, and preference. These early studies dealt with ordinary or mundane conversation as the interactional practice which presents the largest variety of structure. This does not mean that ordinary conversation was the only object of CA or that during these early years CA scholars did not work on other forms of social interaction: Sacks worked on phone calls to a suicide prevention center and on therapy groups, Schegloff worked on emergency calls to the police, and so forth. Conversation is based on a set of practices or methods which are both context-free and context-dependent and offers a reference model for the description of interactional formats that can be found in a variety of social settings. In this sense, ordinary conversation is a “master institution” that exists, and is experienced, prior to institutional forms, encompassing a large array of practices, purposes, rules, and inferential frameworks (Drew & Heritage, 1992).

From the late 1970s on, an increasing number of studies have dealt with (mainly audio) recordings documenting institutional and professional interactions in various naturalistic settings. Institutional talk appears as characterized by distinctive turn-taking systems and sequence types which are a specialized, reduced, or structurally adapted version of formats described in ordinary conversation (Heritage, 1984, pp. 239–40).

For example, in broadcast interviews the sequential organization of the interaction is restricted to the question–answer adjacency pair and an asymmetric distribution of the first and the second pair part among the participants (one being specialized in asking questions and the other in answering them), whereas in ordinary conversation questions are one among a range of possible actions and are not always produced by the same participant. The format of the questions is also specialized in broadcast interviews, with a preface introducing the question: although this preliminary can be pursued through various turn construction units, the interviewee generally waits for the completion of the question before speaking, whereas in ordinary conversation possible transition-relevance points can be used as an occasion to legitimately self-select. Moreover, contrary to conversation, where preliminaries are used for projecting the next action, in the broadcast interview they are used in the service of other tasks, such as providing background information or inserting critical and challenging views, since the participants are already oriented to the question and therefore the question does not have to be announced as such (Greatbatch, 1988; Schegloff, 1988/9).

This kind of analysis has made it possible to identify the specific sequential formats that configure and constrain the opportunities to speak and to initiate actions—as they are shaped by the institutional context but also reflexively construct it—in a number of institutional interactions. Therefore, for example, classroom interactions are characterized by one speaker, the teacher, other-selecting the pupils and by sequences expanded by third evaluative turns (McHoul, 1978; Mehan, 1979); broadcast interviews are characterized by the absence of continuers and of receipt tokens such as “oh,” and these practices orient toward an overhearing mass media audience (Greatbatch, 1988; Clayman & Heritage, 2002); police call openings are characterized by reduced and compacted sequences (Whalen & Zimmerman, 1987), and so forth. Some types of sequences can be found in both institutional and ordinary contexts, such as the “perspective display series” for announcing bad news (Maynard, 2003), but appear to have a more rigid and reduced structure in the former than in the latter.

This kind of observation has made it possible to develop a cumulative body of knowledge about the organization of institutional talk-in-interaction in various settings (Heritage & Clayman, 2010), such as debates in courts, medical consultations, public speeches, or standardized survey interviews. Moreover, this kind of observation has opened up the possibility of a comparative analysis of different forms of social interaction in context (Drew & Heritage, 1992, p. 19; Arminen, 2005) in terms of different levels of organization, such as turn taking, sequence organization, openings and closings, and the overall organization of interaction.

These analyses have a series of important consequences for the articulation between interactional order and institutional order. Instead of starting with an *a priori* categorization of context which would act as a set of pre-existing constraints imposed on institutional interactions, CA considers that the context is created and maintained through the recurrent and pervasive interactional practices of the participants. For example, the institutional context of a call to an emergency service is achieved through the way in which participants treat the call, manage it, and retrospectively refer to it as an emergency call (Zimmerman, 1992). Context is reflexively achieved by the participants orienting to its institutional features, which are procedurally consequential (Schegloff, 1991) for the way in which talk is organized in its details.

Thus, although analysis focuses in the first place on the organization of social interaction, it aims at describing not only interactional practices but also the institution as it is managed, reproduced, and eventually transformed in and through interaction (Heritage, 1984). For example, in her study of work meetings, Boden (1994) shows that meetings reveal and achieve at the same time the institutional structures in action: A company or an institution is maintained, renewed, and transformed through the way in which its members interact together, for example by adopting specific participation frameworks, by favoring specific chairman’s techniques, and so forth, either in formal or in informal meetings: “it is within these local sequences of talk, and only there, that these institutions are ultimately and accountably talked into being” (Heritage, 1984, p. 290).

Ethnomethodological Studies of Work

In parallel with CA’s work on institutional settings, a long tradition of studies of work characterizes EM—the latter having been influential for the former, sharing with it a major concern for the study of social practices as they are methodically and indexically organized. EM studies of work began with fieldwork done by Garfinkel on the work of jurors deliberating guilt or innocence (1967, pp. 104–15), coroners determining cause of death (1967, pp. 11–18), and personnel staff keeping clinical reports (1967, pp. 186–207), and continued

with a rich series of in-depth ethnographies of criminal justice and police (Bittner, 1967), coroners (Sudnow, 1967), and correctional facilities (Wieder, 1974).

Whereas CA studies are based on recordings of naturalistic occurrences of work activities, EM studies rely more on ethnographic fieldwork and on a diversity of sources. Their focus is on the way in which members accomplish their everyday work in an accountable way, on their skilled competence in achieving it, and on the way in which this work achieves, reproduces, and adjusts to the normative order of the institution.

Later on, various studies of work were initiated in technologically complex professional settings—in part supported by the Xerox Research Centre Europe, where Button initiated a series of studies of the locally situated organization of work activities, with the aim of integrating local relevancies, methodical practices, and skills in the technological infrastructures expected to support professional practices (Button, 1993). Studies dealt with topics such as the coordination of work in big enterprises, the emergence of “virtual organizations” and distributed teams, and the conception of computer programs or new technological tools.

Another series of studies focuses on the work of discovering sciences (Lynch, 1993), describing the highly specialized competences and the practical work of research teams (such as astronomers discovering a pulsar, neurophysiologists engaging in “shop talk” during their experiments, or mathematicians writing theorems). These analyses focus on the detailed work involved in performing competently specialized tasks specific to each setting.

These studies contribute to some core EM issues. First, they deal with a central EM notion, *accountability*: The organization of the work setting is based on the fact that participants’ action is available as publicly scrutinizable and mutually recognizable in the work setting. This “observable-reportable” character is further enhanced and made particularly explicit in administrations, companies, and institutions, where infrastructures and technologies support the constitution and maintenance of files, archives, and reports. Second, these studies are interested in the role of rules, procedures, and regulations in the production of action. They show that work practices cannot be specified by rules and they are not produced by following rules—although they can retrospectively invoke rules in order to make sense of the circumstances and justify the outcomes of an activity (see Suchman, 1987). Third, the accountable and methodical achievement of work and expertise reveals practices of mundane reasoning, embodied courses of practical reasoning that constitute the situated rationality of everyday and specialized institutional activities (Garfinkel, 1967; Lynch, 1993).

Workplace Studies

Whereas the study of institutional talk-in-interaction has been focused on the specific sequential organization of institutional interactions and their reflexive and mutually constitutive relation with the institutionality of context, WPS have been focusing on the complex articulation between professional practices and their ecology, with a special emphasis on the material, technological, and spatial context of the workplace (Luff, Hindmarsh, & Heath, 2000). Inspired both by CA studies of institutional talk and by EM studies of work, WPS have focused on “centres of coordination” (Suchman, 1993) such as airport and underground control rooms, where the organization of interaction is highly sensitive to a fragmented and complex ecology, multiple simultaneous activities, multiple participation frameworks, copresent and distant exchanges, and activities mediated by computer and technologically.

Two projects played an important role in this context: The first is the study of an airport initiated by Suchman at Xerox PARC, including intensive videotaping of various locations, focusing on persons at work and producing close-up views of the documents and screens

they were using (Suchman, 1993; Goodwin & Goodwin, 1996). The second is the study of the line control rooms of the London Underground initiated by Heath and his colleagues (Heath & Luff, 2000), focusing on the coordination of multiple copresent and distant activities.

Over the years, other complex workplaces have been described: press agencies, architectural studios, financial centers, archeology sites, operating theaters, television studios, airplane cockpits, and so forth.

WPS have contributed to a diversification of both analytical topics and methodological practices within EMCA. They have extensively used video recordings for capturing the complexity of the work ecology; in turn, video data have revealed the relevance of multimodal resources (linguistic resources, gesture, gaze, facial expressions, bodily postures and movements), artifacts (objects, documents, technologies as they are situatedly used), and environment (spatial organization of the workplace) for the analysis of the sequential organization of action, multiparty interactions, and multi-activity.

Moreover, video data in complex specialized settings could not be analyzed in the same way as those in familiar everyday settings, but made ethnography necessary. Whereas specific forms of ethnography have been largely used in EM, this topic has been controversial in CA, especially since the work of Moerman (1988), which invites a “culturally-contexted CA” and advocates a combination of ethnography and CA. Ethnography in general has been questioned within CA because it is seen as running the risk of imposing exogenous categorical and typological characterizations on the setting, the participants, or the activities before examining the details of talk and conduct in order to demonstrate the procedural consequentiality of relevant categories to which participants incline (Schegloff, 1991). Nevertheless, WPS have shown that ethnographic fieldwork can be done from an EM and CA perspective, and is even necessary for accessing settings that are generally closed to the public and unfamiliar to the researcher. In this case, ethnographic observations provide information about the research site and serve as a form of proto-analysis helping to identify the relevant activities *in situ* and enable the adequate organization and arrangement of the recording devices (see Maynard, 2003, pp. 64–79; Mondada, 2006; Heath, Hindmarsh, & Luff, 2010).

Conclusion: Analytical, Methodological, and Applied Contributions

Since the development of EM and CA in the 1960s, a diversification of the field has occurred, expanding the empirical settings studied, the kind of data collected, and the issues and topics treated by the analyses. The study of institutional talk-in-interaction, EM studies of work, and WPS exemplify this diversity and at the same time strengthen the common focus on the detailed analysis of the situated practices and interactional formats which achieve institutional order.

These approaches have provided substantial descriptions of the specificities and system-aticities of institutional and professional practices. They have contributed to the understanding of the reflexive relationship between action and context, and the “procedural consequentiality” (Schegloff, 1991) of the institutional constraints on the sequential organization of interaction; they have highlighted the practices through which participants recognize and make recognizable the skilled, expert, specialized conducts and reasonings in which they are engaged; and they have shown the configuring importance of technologies, artifacts, and documents in the organization of these activities.

Moreover, by engaging in detailed analysis of the complexity of institutional and professional contexts, these approaches have provided important advances in the methodologies

for documenting them—on the basis of a careful study of naturalistic settings. CA analysis of institutional talk-in-interaction has exploited the fine-grained details of audio recordings to show their relevance for the sequential organization of talk. EM studies of work have insisted on the researcher's competence in the observed practices—what has been called the “unique adequacy,” that is, the researcher's ability to see the phenomena studied from a member's perspective rather than from the perspective of the classical sociological literature—and developed a specific form of ethnomethodologically informed ethnography. WPS have insisted on the importance of the body, material environment, and artifacts, and on the consequent necessity of video recordings and careful analysis of the multimodal details of the organization of action.

Last but not least, these approaches have contributed not only to substantial analytical insights but also to applied issues, stressing the practical consequences of their analyses.

Societal contributions by CA studies—for example in medicine, in education, and in professional training—have been discussed within the last decade under the label of “applied CA.” In proposing the term, ten Have (1999) points to two very different aims: On the one hand, the term has been used to refer to studies focusing on specific terrains and their specific organizational features; on the other hand, it has referred to analyses which aim at various forms of social intervention for the training, counseling, and empowerment of social actors. The former does not always imply the latter, and the latter should not obscure the fundamental analytical contributions made by the former. They can be seen as mutually strengthening each other: Systematic analyses of institutional practices not only enrich the scientific literature but can also empower practitioners. For example, the detailed study of the organization of medical consultations, their opening, the reason for the visit, history taking, prescription of drugs, and so forth shows that the way in which a doctor formats these sequences has consequential effects on the opportunities for the patient to voice his or her concerns and on his or her acceptance of the doctor's recommendations (Heritage & Maynard, 2006). These observations can be crucial for the training of medical personnel, for the development of a patient-centered medicine respecting the patients' knowledge and expertise, and for developing medical prevention programs.

Some EM studies of work have also been oriented toward applied concerns, mainly within the field of technology and participative design, promoting design centered on users and supporting their detailed situated practices. In this context, Button and Dourish (1996) introduced the idea of “technomethodology,” referring to the integration of EM analytical mentality into the very practice of designers, inviting them to adopt an EM perspective on the technologies and the uses they support. This program resonates with Garfinkel's proposal to develop “hybrid studies” (2001, pp. 100–3), where the description of the practices of assembling, making accountable, and achieving an activity, a structure, and an order is done in a perspective converging with the concerns and the agendas of the professionals involved in these same practices.

Likewise, by focusing on the intricate articulations between work and its ecology, between the sequential organization of talk and the embodied organization of spatially situated participation frameworks, between action and technology, WPS have been strongly engaged in interventions in professional settings. Their focus on the situated use of technologies has been important for user-centered design of new technologies and within the field of computer supported collaborative work (CSCW). In this context, they contribute to the re-specification of the sense and the praxeological configuration of terms such as “collaborative activity,” “decision taking,” “usage,” and “workflow organization”; they attempt to shift the attention of designers from the features attributed to the technologies to the contingent and occasioned way in which participants use them in their ordinary practices, to think about technologies as supporting (vs. constraining) everyday work practices.

By engaging with a diversity of institutional and professional settings, by providing rich audio- and video-recorded materials documenting the skilled practices routinely taking place within these social practices, the studies of institutional interaction in CA, EM, and WPS contribute to key advances in analytical and conceptual issues as well as to innovative modes of intervention.

Conversation Analysis and Interaction in Standardized Survey Interviews

DOUGLAS W. MAYNARD AND NORA CATE SCHAEFFER

Surveys use questions to collect measurements from a sample in order to estimate characteristics of a population. The “objective” data obtained by survey interviews are achieved in the interaction between respondents and interviewers who have been trained to behave in a standardized manner. Over the years, both critics and practitioners of standardized survey interviewing have considered how the fundamentally social nature of the interview affects the data produced there. Both groups consider the interaction between the interviewer and respondent when they evaluate the quality of survey data. Critics present examples of interactions that depart from ordinary conversation as evidence that the resulting data cannot be valid. Practitioners suggest that surveys are about measurement rather than meaning in a conventional sense and view such individual incidents as leading to measurement error that results from unusual circumstances or “bad” survey questions. They also consider that adherence to rules of standardization improves the overall quality of the data in the aggregate by increasing reliability. We consider these issues by reviewing the meaning of standardization, the role of tacit knowledge for conducting and participating in the interview, and recent conversation analytic (CA) studies of interaction during survey calls.

Standardization

Fowler and Mangione (1990, p. 35) have codified four principles of standardization as comprehensive, grounded in reasoned understanding of the interview, and refined through many years of practice and observation:

1. Read questions as written.
2. Probe inadequate answers nondirectively.
3. Record answers without discretion.
4. Be interpersonally nonjudgmental regarding the substance of answers.

Survey researchers would probably universally accept these principles, although specific practices derived from these principles can vary. At various sites, researchers and staff charged with supervising field operations have developed their own specifications for training interviewers, derived from such general principles (Viterna & Maynard, 2002).

Standardization does not eliminate the effect of the individual interviewer on the individual respondent. An interviewer who follows the rules of standardization might react to a respondent’s ambiguous answer by repeating all the response categories, for example. From the point of view of standardization, this kind of influence would be preferable to alternative behaviors such as using beliefs about the respondent’s likely answer to choose a particular response category for the respondent to confirm. If standardization were comprehensive and perfectly implemented, we could say that the interviewer did not affect responses—in the very specific sense that the effect of any interviewer would be

the same as the effect of any other interviewer. That is, interviewers who are operating in a standardized manner should be interchangeable.

Listening to a survey interview, it is easy to conclude both that standardization is essential and that it will never be perfectly and comprehensively achieved. This is because no set of rules is complete or covers every contingency. If such a set were somehow developed, it would be beyond the capacity of human interviewers to remember and apply. And so survey practitioners often must accept data produced in “messy” interactions as good enough for the purposes and budget at hand. Survey practitioners explicitly or implicitly recognize that interviewers inevitably must alternate between the rules of standardization and supplementing those rules (Maynard & Schaeffer, 2002). That is, interviewers, along with respondents, deploy resources of an “interactional substrate” (Maynard & Marlaire, 1992)—basic skills for engaging meaningfully—in pursuit of answers. These skills are presumed by and yet largely ignored in the rules of standardized interviewing.

Tacit Knowledge as Deployed in the Survey Interview

Those who are discontented with strict interpretations of standardization may be reflecting an explicit or implicit understanding of the necessity for what Polanyi (1958, p. 20) calls tacit knowledge, which, as part of survey interviewing, has received increased scholarly and practical attention. From a CA perspective, one form in which tacit knowledge about how to gather information is exhibited is through the use of an “interviewing sequence” that unfolds in three turns: (a) question, (b) answer, and (c) acknowledgment. For example, the parts of two interviewing sequences are indicated with arrows in excerpt (1). (FI = female interviewer; FR = female respondent.)

(1) [Maynard & Schaeffer (2002, p. 15), normalized]

- 01 FI: okay, and now we'll get started.
 02 FI: 1 → first, how many persons live in your household counting
 03 all adults and children and including yourself?
 04 FR: 2 → four
 05 FI: 3 → okay and now we have some questions about government
 06 agencies.
 07 FI: as you know, every ten years there is a census of
 08 the population of the United States.
 09 FI: 1 → how confident are you, that the census bureau
 10 protects the privacy of personal information about
 11 individuals and does not share it with other
 12 government agencies?
 13 FI: very confident, somewhat confident, not too confident,
 14 or not at all confident?
 15 ((silence))
 16 FR: share it with what other governments?
 17 FI: well the question doesn't specify, but it says other
 18 government agencies
 19 FR: 2 → oh. probably very confident.
 20 FI: 3 → okay. people have different ideas about what the census
 21 is used for . . .

Not all survey questions appear in this three-part paradigmatic format, with an “okay” or other receipt object such as an acknowledgment in the third position (Schaeffer & Maynard, 1996, pp. 71–2). Often, the acknowledgment by the interviewer is omitted, which results

in a two-part question–answer sequence. For example, when interviewers have a block of questions to ask about a single topic, they tend to omit the acknowledgment and produce two-part sequences until the block is completed, at which point they return to the paradigmatic three-part sequence.

Analyzing the interviewing sequence as a generic form can remind us that the survey is only one type of “interview.” Dictionary definitions, for example, suggest that the interview is a “formal consultation” used to evaluate qualifications or “a meeting at which information is obtained (as by a reporter, television commentator, or pollster) from a person” (*Webster’s Ninth New Collegiate Dictionary*). Accordingly, the survey has a relationship to other interviews, all of which use the interviewing sequence but which vary in discrete ways (including how the third-turn acknowledgment is configured, as we discuss below). For example, physicians and nurses often interview their patients to obtain a medical history; teachers and psychologists interview students as part of teaching and testing activities, employers interview prospective workers in making hiring decisions, and newscasters interview government officials and others as part of their programming. The survey can be compared to these other interviews to specify some of its distinctive characteristics.

Although the survey interview has long been described as a “conversation with a purpose” (Bingham & Moore, 1924, cited by Cannell & Kahn, 1968), survey interviews differ from conversations in substantial and important ways (Schaeffer, 1991). However, administration of the survey is like interviewing behavior in other settings including ordinary conversation (where one participant may casually solicit facts or opinions from another) and institutional settings such as schools, courtrooms, and news organizations in its reliance on tacit knowledge and taken-for-granted procedures. These interactional skills are used by the interviewer in producing questions, the recipient in answering them, and the interviewer yet again in acknowledging or not in particular ways. Although the survey shares generic practices with other interview forms for asking, answering, and acknowledging answers, it is relatively distinctive in its practices for maintaining the neutrality of questions and acknowledging answers without evaluating their content. Studies of interaction in the survey interview recognize the three-part interviewing sequence or its two-part variant as base forms for the interview. There are, however, different approaches to studying this interaction.

Approaches to and Recent Studies of Interaction in the Survey Interview

Since the early 1990s, the methods used to study what happens during the survey interview and the goals of those studies have become more diverse. Explicitly or implicitly, research efforts recognize how tacit knowledge is used in accomplishing a survey interview, but investigators take different approaches to locating how this knowledge is used and the effects of tacit knowledge on data quality. For the sake of simplicity, we categorize these approaches according to whether the research considers turns of talk in the interviewing sequence as the interviewer’s or respondent’s “unilateral” productions, or regards these turns as cooperatively, collaboratively assembled and therefore as “bilateral” productions. The first approach, called “interaction coding” or “behavior coding,” can only be briefly mentioned, and includes studies such as those pioneered by Cannell, Fowler, and Marquis (1968), along with slightly later studies by Morton-Williams (1979) and Brenner (1982). Related to these are experimental studies that examine differences in interviewer styles (Dijkstra & van der Zouwen, 1988). Although researchers examine how the interviewer’s

behavior influences a respondent's answer and how this answer may affect the interviewer, they regard each of these turns as the speaker's own unilateral production, and the main tasks have been to identify indicators of measurement error in the respondent's behavior and errors on the interviewer's part or in the design of questions. Recent experimental research has incorporated a more nuanced understanding of how interview data involve the collaborative "grounding" of understanding (Clark, 1996). Designing protocols that recognize this feature by permitting a conversational style of interviewing may improve response accuracy, although at the expense of increased time to complete the interview (Schober & Conrad, 1997; Belli, Shay, & Stafford 2001).

The collaborative view of survey interviewing is implemented most consistently in CA studies. One of the earliest was Suchman and Jordan's (1990) publication, which expressed reservations because ordinary resources for establishing shared understanding in conversation are prohibited in the survey interview. Their critique, which highlights how the interview imposes external rather than local control, restricts elaboration on answers, and minimizes the resources of repair, suggests how the interview differs from and is inferior to conversation in the establishment of mutual understanding and meaning, rather than what constituent properties characterize the performance of the survey as a standardized interview for purposes of social measurement. Schegloff (1990), in a response to Suchman and Jordan, suggests that inquiry is possible into features of the survey interview as having their own integrity, and that all talk-in-interaction embodies organizational problems having to do with turn allocation; repair of troubles in speaking, hearing, understanding, and so forth; and a variety of other matters depending on the nature of the survey and its substantive topic. For example, Schaeffer and Maynard (2002) have examined "occasions for intervention" on the part of interviewers when respondents either ask for clarification (as at line 16 in excerpt [1] above) or, rather than choosing a response category, produce "reports" that indicate uncertainty and offer an unstated upshot as a kind of proto-answer.

A monograph study is Houtkoop-Steenstra's (2000) study of question-and-answer sequences during the survey interview, although the book also uses Goffman's (1979) concept of "footing," and shows how interviewers and respondents skillfully exhibit a variety of participation statuses or stances relative to the talk and task at hand. Houtkoop-Steenstra also addresses such topics as redundant questions (those for which a respondent has already provided relevant information), the structure of question turns, and the field coding of questions.

Another major CA work on the survey is the edited volume by Maynard, Houtkoop-Steenstra, Schaeffer, and van der Zouwen (2002), with sections on theoretical orientations, recruitment to the survey, interaction during the question-asking portion of the interview, and issues concerning data quality (transcription, coding, and technology). More recent research on recruiting survey participants includes Maynard, Freese, and Schaeffer's (2010) study of how potential respondents present interactional environments that are relatively discouraging or encouraging, and how, in response, interviewers may be relatively cautious or presumptive in their approach. It turns out that a significant matter in obtaining participation is whether interviewers are able to make the request in the first place; that is, interviewers' ability to "tailor" behavior to the interactional environment can affect progress to a point at which a request can be produced, as well as the form the request takes. This line of CA research follows the Groves, Cialdini, and Couper (1992) suggestion that interaction is one of the critical elements in a theory of survey participation, and that interviewers increase the chances of obtaining participation by tailoring their scripted instructions. This means engaging in a continuous search for cues about a householder who answers the door or telephone, and applying the appropriate persuasive messages in relation to those cues.

Conclusion

Overall, along with traditional, more unilateral approaches to studying interaction, CA and its orientation to the inherently collaborative nature of the interview contribute to understanding the social organization of this approach, how to improve the survey itself, and how to increase cooperation with requests to participate in surveys.

Conversation Analysis and Interactional Linguistics

FRIEDERIKE KERN AND MARGRET SELTING

Introduction

Interactional linguistics is grounded on the premise that language should not be analyzed in terms of context-free linguistic structures but as a resource for the accomplishment of actions in social interaction. With this in mind, interactional linguistics takes an interdisciplinary approach to a linguistic analysis that aims at an understanding of how language is both shaped by and itself shapes the actions it is used for. Interactional linguistics combines an interest in linguistic phenomena and structures with the theory and methodology of conversation analysis (CA) and contextualization theory (CT). It is conceptualized as an interface between linguistic analysis and the analysis of social interaction.

Basic Assumptions

Studies in interactional linguistics aim at a description of linguistic phenomena as resources for the construction and organization of practices and actions/activities in interaction. In contrast to the traditional Saussurean and Chomskyan view of language as a system of signs that can be described without reference to the context in which it is used, interactional linguistics adopts the view that language use is fundamentally context-sensitive, that is, practice-, action-, sequence-, and recipient-oriented. Interactional linguistics maintains that linguistic analysis should acknowledge the fact that language is used in and for particular tasks and purposes of interaction, and that, as a consequence, linguistic phenomena need to be analyzed with regard to the conversational actions they are deployed for and the sequences they are embedded in. Within this framework, language is conceived of as an ongoing, emergent product in a social semiotic event; the specific structures of spoken language are analyzed as meaningful and actively deployed resources for the accomplishment of conversational goals or tasks at hand.

The aim of interactional linguistic description is, among others, an underpinning of interactional, in particular CA, sequential analyses by investigating in detail the role of linguistic resources in (cueing or steering) participants' situated construction and interpretation of practices and actions in social interaction. For this, participants' practices and actions are decomposed into their constitutive linguistic and other structures. Interactional linguistics aims at a description of both the forms and functions of linguistic phenomena in talk-in-interaction at all levels—that is, as lexico-semantic, syntactic, phonetic-prosodic, or complex rhetorical or stylistic structures and resources—with reference to linguistic regularities and rules on these levels. It aims at a functional description of linguistic structures by reconstructing how the decomposed linguistic resources are routinely combined and methodically used in particular locations and sequential contexts in order to fulfill their role in the cueing of interpretations of practices and actions in social interaction. For

this, interactional linguistic analysis can—as indicated above—start from either linguistic forms or interpreted practices and actions in interaction.

Historical Development

Interactional linguistics builds upon and is strongly influenced by CA. CA's primary research interest is the description of participants' methods for the organization of social interaction. CA is not interested in investigating the linguistic details of those methods in a systematic way. However, CA's fundamental interactional perspective on language has inspired many linguists.

For the development of the interactional linguistic research perspective, three approaches have been most relevant:

1. In the 1980s, British linguists and phoneticians began combining phonetic analysis with CA methodology. They showed that phonetic structures are systematically shaped by and used for the accomplishment of tasks in interaction. They argued that such phonetic structures should hence be described as products of and resources for the organization of the speech exchanges in which they are produced (e.g., French & Local, 1983).
2. After earlier work in linguistic anthropology had described syntactic structures with reference to discourse structures, scholars based in the USA developed a new approach to discourse-functional linguistics which headed in similar directions in their aim to combine linguistic analysis and CA sequential analysis, focusing primarily on the role of syntax, later also prosody, in sequential social interaction (e.g., Fox, 1987; Ford, Fox, & Thompson, 1996).
3. In the German research context, a group of linguists combined the theory and methodology of CA with the insights of CT in investigating the role of prosody and syntax in spoken language in interaction (e.g., Auer & di Luzio, 1992; Couper-Kuhlen, 1993; Selting, 1995). CT claims that participants in interaction deploy linguistic and paralinguistic features to suggest and evoke interpretive frames which are used by participants to "construct" a context of interpretation, allowing them inferences about "what is going on" in the speech event (see Gumperz, 1982). CA and CT constitute the theoretical and methodological basis of research in interactional linguistics.

Research Principles and Methods

Research in interactional linguistics is strictly empirical and grounded in databases of naturally occurring talk-in-interaction. The analysis includes a description of linguistic forms and structures as well as an account of their functioning as a relevant resource in talk-in-interaction. The analytical categories to be developed are understood as an integral part of the sequential context in which they occur. As far as possible, they are derived directly from the data. Categories need to correspond as closely as possible to those that the participants themselves can be demonstrated to orient to in interaction (participant categories). Categories are validated or "warranted"—that is, demonstrated as indeed relevant for the participants' orientation—by showing that and how recipients in their next turns orient to them. Grammatical analysis, for instance, is not to be guided by a priori traditional concepts such as "clause" or "sentence." Instead, linguistic units and constructions are viewed as the result of an ongoing, real-time process of coordination and interaction between the participants, by-products of their construction of practices and actions in conversation.

Methods of validation in interactional linguistics draw mainly on principles of sequential analysis. Linguistic structures are reconstructed as interactionally achieved and interactionally relevant phenomena. The following five types of evidence are employed for grounding analytic categories in the data themselves:

1. The relationship of the device to just prior turns. Linguistic phenomena in turns are often shaped by features of prior turns.
2. Co-occurring evidence within the turn. Syntactic, lexico-semantic, and prosodic cues may be used cumulatively, supporting each other in order to suggest specific interpretations of turns.
3. Subsequent treatment of the interactional device in question. Analytical categories may be discoverable and shown as relevant by examining following talk in order to see how a turn is being dealt with by participants.
4. Discriminability of the interactional device. The systematic comparison of a linguistic category with other categories may shed light on its specific function.
5. Deviant cases in the use of the device. Even though at first sight deviations may contradict the hypothesized regularities, they in fact often confirm them on a deeper level. Participants may respond to deviant cases violating routine expectations in ways that reveal their orientation to just those routine expectations: For example, speakers may account for their not conforming to the expectations, or recipients may explicitly demand actions conforming to expectations.

Objects of Research

Interactional linguistics is interested in all objects of research that are grounded in the use of language in social interaction. There are basically two possibilities of starting a study in an interactional linguistic framework. One way is to select a conversational practice or action/activity type as a starting point, and to reconstruct the linguistic devices with which it is methodically accomplished. The second way is to select a specific linguistic structure as a starting point, and to investigate its methodical use and functioning for the accomplishment of verbal actions. Research can be either language-specific or crosslinguistic. Crosslinguistic research allows insights into the ways in which the accomplishment of conversational practices and actions may be shaped by the linguistic resources provided by the specific languages at hand.

So far, most studies have focused on examining the role of devices from either syntax or phonetics-prosody, and the relations between them, for the conduct of interaction (e.g., Auer, 1996; Ford et al., 1996; Selting, 1996; Couper-Kuhlen, 2004). More recently, response particles (e.g., Betz & Golato, 2008) and lexico-semantic structures and devices have also been attended to (e.g., Couper-Kuhlen & Thompson, 2005; Deppermann, 2005). Furthermore, scholars have begun to integrate analyses following empirical approaches to construction grammar into the interactional linguistic endeavor (e.g. Couper-Kuhlen & Thompson, 2005; Günthner & Bücker, 2009). Most recently, students of interactional linguistics have begun to systematically include multimodal aspects of language use into their analyses of talk in social interaction (Gülich & Couper-Kuhlen, 2007; Selting, 2010).

Linguistic structures are described with respect to their role in the following practices and actions in social interaction: (a) the construction of turns and units smaller than turns—turn construction units (TCUs)—in and for interaction, (b) the organization of turn taking, (c) sequence organization, (d) the formation of practices and actions, and (e) the constitution of conversational genres and styles.

An additional area of interest is the study of the ways in which linguistic structures and phenomena are used and modified in specific interactional settings and participant constellations, such as in institutional settings (e.g., Heritage & Clayman, 2010), in interactions with and between children and adults (e.g., Wells & Corrin, 2004; Kern & Quasthoff, 2005), or with and between participants with communication disorders (e.g., Goodwin, 2010).

Findings

Since the early 2000s, numerous empirical studies have demonstrated that the construction and interpretation of conversational practices and actions depend on their linguistic structure as much as on their positioning within an action sequence. In particular, it has been shown that prosody and syntax play important roles for the construction of smaller conversational units, such as TCUs, as well as for the organization of thematic and sequential (dis)coherence, for action construction and the signaling and management of affectivity.

Conversation Analysis and Interview Studies

GABRIELE KASPER

Conversation analysis (CA) approaches any kind of interview from a set of empirically grounded premises.

1. Interviews are a form of locally accomplished social interaction.
2. Interviews are jointly produced by interviewer and respondent.
3. Participants' talk in the interview accomplishes a range of social actions, stances, and identities.
4. All features of the participants' interactional conduct may shape the flow of the activity and generate the interviewee's responses.

With these premises, CA's approach to interviews sets itself apart from the prevalent treatment of interviews in the social sciences. "Prevalent treatment" may seem an objectionable description, considering the wide variety of theoretical perspectives on interviews, their social and cultural contexts, interview researchers' disciplinary and political agendas, and interviewing formats and styles (Gubrium & Holstein, 2002; Roulston, 2010). Yet the differences between, for instance, social constructionist (Chavez, 2006), phenomenological (Kvale & Brinkman, 2009), postmodern (Fontana & Prokos, 2007), and feminist (Hesse-Biber & Leavy, 2007) orientations to interviews, and the diversity within each of these (partially overlapping) groups, recede into the background when it comes to the analysis of interview data. The practice of coding the data for recurrent themes that speak to the study's theoretical orientation and investigative purpose, read off from the interview transcript (e.g., Chavez, 2006; Kvale & Brinkman, 2009), de facto treats the interview as a self-evident instrument for gathering information about respondents' social and mental life, a transparent conduit to the purportedly situation-transcendent content of a person's mind. Epistemological avowals to the contrary notwithstanding, this data treatment builds on a transmission model of communication, in which language is seen as a neutral medium that requires no particular analytical attention, while interactional organization and non-linguistic semiotic resources are disregarded altogether. Although anthropologist Charles Briggs issued an early warning that "interview techniques smuggle outmoded preconceptions out of the realm of conscious theory and into that of methodology" (1984, p. 3; Mishler, 1986), the practice of interview analysis in the social sciences and in applied linguistics in particular has overwhelmingly remained unaffected (Talmy, 2010).

Research interviews share with interviews conducted for other purposes a turn-taking system that reflexively constitutes an activity as interview. Unlike ordinary conversation, turns in interviews are distributed through "action (or 'turn-type') preallocation" (Heritage & Clayman, 2010, p. 37), that is, one party asks questions and the other party answers them. As first pair parts in an adjacency pair, all questions constrain the range of possible next actions and their format and therefore create a momentary asymmetry between questioner and answerer. The organization of the interview ties the questioning and answering to the categories of interviewer and respondent and thereby lends the entire activity an

inbuilt asymmetry—which, however, does not necessarily remain unchallenged, as in cases when respondents resist answering a question as projected (see examples below).

Studies conducted from the perspectives of ethnomethodology (EM), CA, and discursive psychology (DP) examine the methods by which participants accomplish different types of research interview as orderly social activities. The standardized survey interview and the qualitative interview are two contrasting dyadic interview formats. A third major type of research interview, the focus group, has been less prominent, especially in applied linguistics. Focus groups can be more or less prestructured (Morgan, 2002, for overview), but all varieties are organized as moderated group discussions of a topic in which the participants are experts or stakeholders. In contrast to the dyadic interview, participants in focus groups interact with each other, not only with the moderator. In informal focus groups, turn pre-allocation is relaxed or minimized. Consequently their interactional organization tends to be more conversational, that is, party-administered and locally managed.

Survey interviews are designed to minimize random error and bias in order to afford reliable and valid social measurement. Interview questions are therefore prestructured through a scripted interview schedule, and allowable response formats are strongly constrained. And yet, as survey researchers are the first to acknowledge, it is impossible to entirely bring the contingencies of interaction under the control of a prescriptive interview regime. At unpredictable moments, interviewers and respondents can be seen to depart from the standardized protocol, resort to their commonsense interactional competencies to resolve local problems in the interaction, and revert to the formal institutional practice. As an example, Moore (2004) discusses the practice of “projective reporting,” “a device for managing [such] mismatches between presuppositions embodied in the questions and the respondents’ own experiences” (p. 57). In this practice, rather than answering a survey question as projected by the question format, respondents report a circumstance related to the answer. (In excerpt [1], “IF” = female interviewer, “RF” = female respondent.)

(1) [Moore (2004, pp. 62–3)]

- 193 IF: An: 'uh .hh (0.3) did you listen to
 194 an opera ↑music ↓program on radio
 195 (1.1)
 196 RF: Parts of it hhhh [heh-heh]
 197 IF: [.tch Okay] that's okay.
 198 .hh An did you listen to opera music
 199 records tapes or compact discs

The lengthy gap of silence following the interviewer’s question (line 195) flags the question as problematic for the respondent and may indicate that she does not have a response ready to it. In her subsequent response (line 196), she does not answer the interviewer’s polar question with a “yes” or “no” as projected. Instead her response shows what the problem is—whether listening to “parts of” an opera music program counts as listening to “an” opera music program. The turn-final laughter may index the respondent’s uncertainty about whether this is an acceptable answer—precisely one of the problems that now confronts the interviewer, who has to decide (a) whether the respondent’s report qualifies as an allowable answer as projected by the question, and (b) how to code that answer. In other documented instances of projective reporting, the respondent provides an upshot of the report, such as “so I guess yes.” Without an upshot formulated by the respondent, the interviewer has to make her own judgment by inferring from the respondent’s report to the available answer categories. Interviewers sometimes offer candidate upshots to the respondent for confirmation (“so you *did* listen to opera on the radio”), but not in this case. Without an upshot formulated by either participant, the interviewer accepts the report

as a qualified answer in her next turn (line 197) and proceeds to the next survey question (line 198). As Moore (2004) comments, implicit answers and their interpretation are standard interactional practices in ordinary conversation and other forms of institutional talk, but they violate the stipulations of the standardized survey protocol. Yet in order to accomplish “standardization in interaction,” departures from the standardized routine through projective reporting and other commonsense practices are unavoidable members’ methods.

In contrast to standardized interviews, the overall purpose of *qualitative* interviews is to obtain in-depth descriptions and accounts of the participants’ lifeworld. Interview formats that meet this goal are semi-structured or un-prestructured (“open-ended”). Although the interviewer decides what initial questions to ask, he or she typically assumes the role of an attentive listener in order to “give voice” to the participant and encourage long and detailed personal accounts and narratives, told from the respondent’s subjective perspective. Despite the marked difference in purpose, established social science approaches to qualitative interviews share with standardized interviews the view that the interview serves as a window to the participants’ inner world and their perceptions of the world outside—in other words, the interview figures as a *resource* to inform about matters of a different order than the interview itself. From a CA perspective, the main focus of interest is how the interview comes off as an organized social activity, that is, the interview interaction becomes the *topic* for analysis. CA’s concern with the “assembly process” (Holstein & Gubrium, 2004) of interviews has brought into view a range of interactional practices, among them the delivery structure of questions and responses (Grindsted, 2005), speaker-ship allocation (Mazeland & ten Have, 1998), repetition and upshot formulation (Mazeland & ten Have, 1998; Grindsted, 2005), accounting practices (Baker, 2002), reported speech (Buttny, 2003), hypothetical scenarios (Roulston, 2001), and membership categorization and attribution as moral work (Roulston, 2001; Baker, 2002). These and other CA studies attest some of the methodical practices by which interviews come about as the interviewer’s and respondent’s joint interactional accomplishments. By implication, they also show that some prevalent methods in the analysis of qualitative research interviews are prone to undermine the validity of the proposed findings. One such method is to delete the interviewer from the analysis (Potter & Hepburn, 2005) and attribute interview “outcomes” unilaterally to the respondent. Another, related procedure is to read off from interviewee responses themes that are relevant to the theoretically stipulated research goal and treat the interviewee’s comments about such themes as evidence for the person’s memories, experiences, attitudes, perceptions, or similar cognitive states.

The approach to interviews as a tool for excavating the contents of respondents’ minds is embodied in transcripts that delete the details of the sequential and temporal organization of the interview talk and represent the interaction as a written script. Excerpt (2) below, from Speer (2005), illustrates some ways in which the interviewer’s conduct shapes the interviewee’s actions and how respondents manage identities, stake, and interests through the sequential, temporal, and linguistic composition of their turns. The interviewer (Speer) had asked Ben, a man in his mid-twenties, whether he had ever been to a gay bar. Ben described an occasion where he went with his girlfriend and some of her friends (“‘coz she was intrigued’”) and that he was “chatted up” by a man (Speer, 2005, p. 112).

(2) [Adapted from Speer (2005, p. 112)]

- 01 Speer: Was he attractive?
 02 (0.6)
 03 Ben: Phh. (1.8) I s’pose he was reasonably well looking, ↑Yeah.
 04 (1.6)
 05 But you know it doesn’t interest me,

06 (.)
 07 I'm definitely (0.8) not interest(h)ed(h) in(h) men(h).
 08 Speer: hhh.
 09 (0.8)

Five observations: The first and most fundamental point to make is that the topics of Ben's "experience" in a gay bar and his reaction to another man's physical attractiveness would not have come to pass, at this moment in the interaction, and in this particular form, without the interviewer's initial question (whether Ben had ever been to a gay bar, not shown in original) and her "follow-up" question in line 1.

Second, Ben's extended response is inevitably recipient-designed and sensitive to the interactional setup, that is, produced for this particular recipient, a female friend, in a dyadic talk in his home. Were Ben to talk on the topic with other participants in a different location—a group of male friends in a pub, for example—the telling might come out quite differently. With contextually shifting accounts, displays of stances, and (dis)claimed and attributed identities, interview participants orient to the local and relational character of their tellings. "Experiences," "attitudes," or "perceptions" are only available as discursively and contingently produced versions.

Third, the interviewer's conduct visibly shapes the interviewee's response. After her initial question, the interviewer passes up all opportunities for taking another turn and so pursues from Ben multiple expansions of his answer (lines 4, 6, 8, 9).

Fourth, with the temporal, prosodic, and verbal resources that Ben marshals in producing his answer, he treats the matter brought up in Speer's question as a delicate one. To begin with, Ben's answer to Speer's polar question is delayed through an inter-turn gap, a vocalization (*Phh.*) that casts the question as one that he does not have a ready answer for, and a rather lengthy pause. Ben then launches a type non-conforming answer (Raymond, 2003) by indexing epistemic caution (*I s'pose*) and downscaling Speer's description *attractive to reasonably well looking* before adding a type-conforming answer token, *↑Yeah*. The turn-final position of *yeah* and its initial rise bring Ben's answer off as the result of an unpremeditated evaluation rather than something he thought about before. Since the interviewer neither offers a third-turn acknowledgment nor asks another question after Ben's completed answer turn, Ben takes another turn (line 5) in which he counters the possible inference that he might be "interested." The *but*-prefaced turn sets the upcoming utterance in contrast with the preceding, while the epistemic stance marker *you know* frames the following unit as information that is new to the recipient or that the recipient should consider. As such, the *you know* token makes an acknowledgment relevant in the next turn. When none is forthcoming, Ben reformulates the matter-of-fact account *it doesn't interest me* (line 5) as an upgraded (*definitely*), more explicit version (replacing *it* with *men*) with stronger speaker involvement through the active grammatical mood: *I'm definitely (0.8) not interest(h)ed(h) in(h) men(h)*.

Finally, with the laughter toward the end of the turn, Ben discounts the opposite proposition as absurd.

Analytic attention to the interactional practices by which Ben assembles his answer makes visible how participants construct identities and stances in their lives outside of the interview as local concerns at particular moments in the interview interaction. We see, first, that Ben treats Speer's question in line 1 as confronting him with a dilemma, that is, acknowledging another man's physical attractiveness without experiencing erotic desire; second, how he draws on such context-free methods as reluctant concession and disavowing interest to claim the identity of a non-homophobic heterosexual man. In order for participants' methodic interactional practices to become available for analysis, interviews have to be transcribed according to standard CA convention (Potter & Hepburn, 2005).

The study of research interviews from a CA perspective has a fairly short history and consequently, the main task for investigators is to formally describe the procedural infrastructure of different types of research interview. But the social organization of interviews remains a critical concern for investigators also when some topical focus sets the agenda for a study because, as Holstein and Gubrium (2004) emphasize, the *what* in interviews is only available through the *how*.

Conversation Analysis and Language Acquisition

JOHN HELLERMANN

Researchers interested in language in use have used methods from ethnomethodological (EM) conversation analysis (CA) to show convincing evidence for the process of learning as it happens in a turn-by-turn manner in sequences of talk (e.g., Garfinkel, Lynch, & Livingston, 1981; Macbeth, 1994; papers in Markee & Kasper, 2004). Recently, theoretical and practical concerns have motivated researchers using CA to consider the possibilities of observing learning beyond individual interactions, to look longitudinally and propose that learning is observable in changes in practices for interaction (Wagner, 2004; Hellermann, 2007) at different points in time. The practical concerns are developmental (how children learn language), pedagogical (how adults learn additional languages), and vocational (how professionals learn their professions). For much of this research, another practical concern is the expectation of making connections between research and practice.

Due to CA's local and social focus on interaction and the traditionally psychological definitions of learning, such longitudinal investigations using CA methods have raised theoretical and methodological concerns and these questions: What is the theory of language and social interaction that grounds CA methods and what, if any, are the limitations for investigations of learning using that method? In this entry, to illustrate how CA and longitudinal data offer insights into the issue of learning, I will discuss some reasons that CA researchers have chosen to use longitudinal data, and how CA research might conceptualize acquisition or learning. Toward the end of the entry a brief summary of some research using longitudinal data and CA methods to address learning will be presented.

Longitudinal Data with CA Methods

There are at least two reasons for the relatively recent concern of CA researchers with issues of learning and taking on the conceptualization of learning as a social process. The first is the increasing numbers of CA researchers who work in contexts (university departments) where there is interest in connecting research to practice (departments of language pedagogy, child development, and applied linguistics). Researchers in these departments are working with data involving "novices" of some sort who are "in training" in some way. Novices in this sense may be children developing competencies for language and social interaction, adult learners of a foreign language, physical therapy patients, or apprentice professionals in training.

The very fact of investigating the talk-in-interaction of novices strongly implicates the researchers in showing the participants' orientations toward their novice statuses if not the changes that occur during their time as novices. As self-identified and socially identified novices, the participants in these interactions are working toward socially established interactional goals but, by definition, are not yet competent in one or more of these goals. The CA principle that there is order at all times in interactions and that members use their competencies for ordering their social interactions suggests that, in the interactions

of novices, the orientation of participants to their novice statuses and novice competencies will be made visible in their interactions.

Adding a longitudinal focus to the investigation of the sequential nature of talk-in-interaction that novices use to negotiate local contingencies can show participants and researchers differences in the management of those sequences at different points in time. It can as well show the degree to which this management conforms to institutional goals, that is, to the standards of talk-in-interaction of the particular institution, be that the language, the school, the doctor, or the governing board. In many cases, practitioners (often the researchers themselves) have immediate needs to use the findings from research in instructional settings. Funders, administrators, and colleagues rightly look toward researchers for the connection to practice.

A second reason for CA to address learning at this point in time may be the availability of longitudinal data. CA uncovers regular practices for the turn-by-turn sequential formatting of talk in any conversational or institutional setting. A priori regard for contexts or participants is not necessary for this research endeavor, and as a result, data collection is often not purposeful with respect to participants or context. Yet, while purposeful data collection has not become part of standard CA methods, the use of data collected purposefully by other researchers does occur and has been present from the start of CA research (Sacks's, 1992, and others' research on recordings of suicide prevention hotline calls). Recent longitudinal CA research on learning has used longitudinal data collected expressly for the purpose of doing sequential analysis on learning in that context (Wootton, 1994; Forrester & Reason, 2006; Cekaite, 2007; Markee, 2008; Nguyen, 2008; Forrester & Cherington, 2009; Ishida, 2009; Martin, 2009). Others have used data collected longitudinally for other purposes for their sequential analyses (Brouwer & Wagner, 2004; Hellermann, 2007).

CA Methods and Learning

EM and CA consider cognition a visible, social phenomenon (Coulter, 1983; Schegloff, 1991); the conceptualization of learning as also a social, co-constructed process is not an epistemological leap. That conceptualization has been made in various ways and is still underway.

CA methods are not interested in and cannot offer understanding toward neurological or psychological changes that may be part of learning and which are the dominant focus for research on learning in psychology. Like its theoretical precursor EM, CA is interested in the accountable, commonsense methods that members use to accomplish social interactions, accountability that is visible without access to views of electrochemical actions of the brain. It is this foundational understanding of CA that is allowing new insights to be made into learning. Researchers using CA are conceptualizing learning as a visible and co-constructed accomplishment seen in talk-in-interaction (Brouwer & Wagner, 2004; Wagner, 2004) and in the change in language practices seen over time (Hellermann, 2007). CA's focus on details of talk-in-interaction shows how members are accountable to one another for their social organization and allows researchers to discuss learning as a situated and co-constructed process.

Some CA researchers draw on learning theory from outside of CA to ground their empirically based claims for evidence of learning (discussed in Kasper, 2006; Markee, 2008; Markee & Mori, 2009). Situated learning theory (Lave & Wenger, 1991) has been invoked as compatible with CA methods (Hellermann, 2008) given that its main constructs ("joint enterprise," "shared repertoire," "mutual engagement," and "legitimate peripheral participation") conceptualize learning in a co-constructed, situated, and interactional

way (Fox, 2006). CA researchers have brought situated learning theory in at the end of the sequential analysis of the data and used it to help explain the empirical findings of the analysis. When the sequential analysis of longitudinal data involving novices is complete and differences in the sequential practices used by the novice are noted by the researcher as having occurred at different times, the researcher is called upon to speculate on the reasons for these differences. For those interested in situated learning theory, the agnostic stance of the CA researcher doing the sequential analysis is set aside when the analysis is complete, and bodies of knowledge on human interaction are drawn on to take the next step in the analysis (Brouwer & Wagner, 2004; Nguyen, 2008; Martin, 2009).

From an EM perspective, competent members of society have and use their competencies for achieving social order through talk at all times, meaning that every unmarked ("normal") sequence of talk can be seen as local, indigenously organized achievement. If that is the case, the question arises: What might be considered "new" achievements or learning? In linguistics, the commonly held understanding is that a native language is acquired by the early teenage years. With this understanding, language learning researchers generally stop considering the possibility that first language speakers after the teenage years may be "learners." However, with its theoretical grounding in EM, CA methods show that each interaction provides the opportunity for such new achievements when participants use and adapt context-free methods for the particular contingencies of each interaction. Learning, then, is not limited to the category of "novices," be they novice users of a language, children learning their first language, or novice professionals. CA studies of learning focus on novices because they are the participants in whom there is societal and pedagogical interest. They are the participants whose status as members (determined by their accounting practices in talk-in-interaction) is of interest to both the participants themselves and the analyst.

Some Longitudinal Research Using CA Methods

The first longitudinal investigations by a CA researcher are Wootton's studies of his daughter (1994). Wootton's research, as well as more recent child language studies by Forrester (Forrester & Reason, 2006; Forrester & Cherington, 2009), investigates the development of actions through the talk of young children without explicitly addressing a theory of learning. In studies of children, the assumption is that the appearance in the data of a language form or sequential practice is part of the child's language and social development. Given the field for several of these publications (psychology), by implication, this development can be understood as evidence of the development of individual cognitive capacity. CA methods, however, attempt to uncover participants' (even novices') active work to establish intersubjective understanding, and Forrester's and Wootton's research is consistent with these methods, claiming that the newly appearing sequences of talk of the children in their data are visible, co-constructed examples of what is called cognition. This perspective comes through especially in Wootton's description of children's development of language practices as "self-guided" (2006, p. 196).

The research by Wootton and Forrester focused on the interactions of young children (starting at around age 10 months) in at-home settings with caregivers. The research investigated particular competencies of a participant for actions in talk (requests, repair) over a period of several years. As the children faced different interactional contingencies for interaction (different objects in the environment, different participants, different actions), these contingencies were shown to be the contexts for the new forms and practices for talk. The assumption is that the new language forms and practices are needed and develop for use to work with these new contingencies.

Research on adult novices in various situations is complicated by the fact that as adults, novices face different contingencies with a wealth of interactional and social experience. Studies of adults in classroom settings for language learning have traced the practices for talk-in-interaction to perform the same actions at different times (Hellermann, 2007) and how different contexts at different times provide opportunities for learning (Markee, 2008).

Adult novice language users have also been studied longitudinally outside of explicit learning contexts. Ishida (2009) focused on the appearance of a particular language form of one novice user of Japanese (sentence-final particle *ne*) and its use for different functions at different points in time (data over nine months). Although exploratory in nature, Brouwer and Wagner's (2004) study of international business telephone calls showed how learning can be seen in practice, showing how adjustments to greeting sequences were made in the lingua franca telephone interactions of business people at different points in time. Brouwer and Wagner's conceptualization focuses on the active nature of learning as a process—the response and differing adjustments to interactional contingencies.

Two other projects have used CA methods on longitudinal data from work and professional training settings. Martin (2009) reports on an investigation of a CA practice (repair) that was accomplished through talk and physical movement in orthopedic rehabilitation. In this case study, data were collected on 22 occasions over the course of nine months. Martin found that during the interaction between a physical therapist and patient, a patient learned to accomplish the therapeutic movement independently over the course of the nine months. During repeated therapy sessions, the patient's orientation to the movement necessary for therapy went through three stages: (a) the therapist (other) initiates and repairs the shoulder movement behavior; (b) the therapist (other) initiates repair of the problematic behavior but the patient (self) can complete the repair; and (c) the patient recognizes, initiates, and completes repair of the problematic therapy behavior.

Nguyen's research (2008) focused on pharmacy interns interacting with clients picking up medication at a pharmacy. Nguyen's data included 21 interactions collected over two months. The analysis showed that the repeated participation in the speech exchange system of pharmacist–client provided a context for the intern to develop expert-like practices for opening interactions, giving advice, and transitioning between activities. This change was seen in the way the interns brought the patient in as a ratified participant in the interaction and managed to coordinate their own advice with the doctor's prescription. While Nguyen acknowledges interaction as co-constructed, she sees CA methods used with longitudinal data as allowing focus on the development of one party's competence (the pharmacy intern) for the management of an institutionally devised practice.

Conclusion

EM and CA provide an account of social behavior that focuses on participants' accountability to one another for normative language use. EM studies (and many CA studies) focus on the local achievements of accountability expressed through language as learning without resorting to generalizations beyond the particular contexts in which the learning occurs (Fox, 2006). In addition, CA looks at the role of sequences of language-in-interaction in managing or co-constructing this accountability, and has provided baseline findings from exhaustive empirical analysis, suggesting the possibility for generalizing from particular contexts and doing comparative analyses (Schegloff, 2009). Comparative studies that are done in the interest of seeing learning over time periods longer than single interactions ask: If members hold one another accountable and produce accountable talk and action for members, how do novices produce such accounts and orient to accountability in member-like ways, and how do such practices change over time as contexts for language use change

over time? The CA research that has focused on the interactions of novices suggests that the accountability is there (for adults at least) and that changes in the practices for this accountability can be observed both in a turn-by-turn way and in an event-by-event way with longitudinal data.

Conversation Analysis and Laughter

ELIZABETH HOLT

Introduction

Social interaction centers on linguistic elements but nonlinguistic aspects are also crucial. One of these is laughter. It might be thought that laughter is not subject to the kinds of patterns that underpin talk; that it is often simply a spontaneous reaction to finding something funny. But research in conversation analysis (CA) has revealed that this is not the case. Laughter is, in fact, highly organized and is the product of the same kind of ordering that provides for all social interaction. Thus, existing research has revealed regularities in its use in terms of where it occurs in turns and within sequences; in the kinds of interactional environments it occupies; and in the tasks it accomplishes. Research on interaction has also thrown light on the relationship between laughter and humor.

Laughter has often been regarded simply as a response to some humorous stimulus (see Glenn, 2003). But CA investigation of its use in interaction has revealed it to be a far more complex and multifaceted phenomenon that displays its own orderliness and that contributes to the ongoing action sequences in which it occurs. Evidence for this comes from analysis that has investigated laughter in contexts other than where there is something manifestly funny about prior talk. Some of these findings will be summarized below. However, while laughter is not simply a reaction to humor, it is true that laughter does not have meaning in the way that lexical items (as part of the linguistic code) do. Laughter has a referent. In CA this referent is called the “laughable.” According to Glenn, “Placement of a laugh relative to its laughable displays precisely what the referent or laughable is, typically via placement concurrent with or immediately following the object” (2003, p. 49). But specifying the meaning of the term “laughable” is not easy. Glenn (2003) states: “The relationship between laughs and their referents defies consistent labeling, in part, because the term *laughable* glosses over an analytically problematic notion. Virtually any utterance or action could draw laughter, under the right (or wrong) circumstances. This fact dooms any theory that attempts to account coherently for why people laugh” (2003, p. 49).

Recent work on laughter in interaction suggests that, in treating a turn, sequence, or component as a laughable, participants may often be orienting to a cluster of properties concerning the delivery, design, sequential position, and action of the talk (Ford & Fox, 2010; Holt, 2011). Turns containing certain components are recurrently treated as laughables, such as exaggerations (Drew, 1987; Ford & Fox, 2010) and reported speech and enactments (Holt, 2000, 2007).

Laughter regularly occurs in a range of positions in respect of the ongoing talk: (a) within a turn, often interspersing talk toward the end of the turn; (b) at the end of a turn following talk, by the same speaker; (c) as a response to a prior turn; and (d) (less commonly) following a pause, or a response by another participant, where the laughter seems to relate to the speaker’s prior talk. A distinction between laughter and talk is that, whereas speakers commonly avoid overlapping talk, it is acceptable (and sometimes even desirable) for participants to laugh together. Simultaneous laughter is called “shared laughter” (though shared laughter need not be concurrent; Jefferson, Sacks, & Schegloff, 1977, p. 2). Jefferson (1979) has shown that a first laugh can serve to invite reciprocal laughter. Following a

laugh invitation recipients can accept it by laughing; they can decline the invitation, often by overlapping the laughter with talk; or they can remain silent, which may result in the producer of the invitation pursuing laughter. Laughter that occurs without a preceding explicit laugh invitation is “volunteered” laughter (Jefferson, 1979).

The Interactional Environments of Laughter

CA research on laughter in a range of different interactional environments has thrown light on the regularities that underpin its occurrence, and the contribution it makes to the ongoing action sequence. However, it must be remembered that laughter is a slippery device: Because it is not part of a linguistic code it is highly ambiguous and attempts to identify why it is used must proceed cautiously. On different occasions it can have contradictory uses—for example, it can be used to display both affiliation and nonaffiliation—and thus generalizations cannot easily be made. Furthermore, existing research is limited and there is a need for further analysis of laughter in a broad range of sequential environments.

Observations about the interactional uses of laughter have been made, focusing on its use within turns, in pairs of turns, within more extended sequences, and in the wider social context. These are discussed below.

The Contribution of Laughter Within Turns

On occasion speakers produce particles of aspiration during words. Traditionally these have been referred to as laugh particles; however, Potter and Hepburn (2010) refer to them as “interpolated particles of aspiration” (IPAs) because it avoids the presumption that these are the same as laugh particles outside of words. These researchers identify two uses of IPAs: (a) They can be used to mark a lexical item as, in some way, insufficient or problematic; and (b) “they can be used as a resource for action formation, inserted into words to modulate the nature or strength of the action” (p. 1). Laughter toward or at the end of turns has also been seen as modifying the action of the turn. According to Schenkein (1972, p. 366), “*hehe* can be tagged on to the end of an utterance as some kind of insurance that the utterance will not be taken seriously, literally, or in its more typical senses.” Thus, it may be considered a kind of “post-completion stance marker” (Schegloff, 1996), implicitly conveying the speaker’s stance toward the preceding talk. At the same time, as well as potentially modifying the turn, it may also play a role in indicating that a completion has been reached (O’Donnell-Trujillo & Adams, 1983).

Laughter as a Response

Jefferson (1979) showed that laughter recurrently occurs as a response to an invitation to laugh made through laughter in the prior turn.

(1) [Jefferson (1979, p. 81)]

01 ELL: he s'd well I am cheap he said, .hh about the big things.
 02 he says but not the liddle things hhhHA HA[HA HA HA
 03 BIL: [heh heh heh

Ellen laughs at the end of her turn and Bill treats this as an invitation by joining in after two beats. Thus, reciprocation of laughter may affiliate with the conveyed stance of the prior speaker. This can be seen in talk involving reported speech (Holt, 2000), where laughter by the recipient may affiliate with the teller’s stance toward a reported utterance implicitly conveyed through laughter at or toward the end of their turn.

Reciprocating laughter, however, may not always display affiliation. According to Jefferson (1984), laughter in the environment of troubles-telling can display troubles-resistance on the part of the teller.

(2) [Frankel:TC:1:4:SO]

- 01 G: you don't want to go through all the haussle?
 02 S: .hhhh I don't know Geri,
 03 (.)
 04 S: → I've I've stopped crying uhheh-heh-heh-heh-heh,
 05 G: → wuh were you cry:ing?

S laughs at the end of line 4, displaying that she is able to take the trouble lightly. However, G does not treat this as a laugh invitation by reciprocating. Instead he takes the trouble seriously, thereby exhibiting “troubles-receptiveness” (Jefferson, 1984, p. 351). Only in what Jefferson refers to as “buffer topics” (i.e. when the participants have moved away from discussion of the trouble to other—related or unrelated—matters) do recipients recurrently treat the laughter as an invitation to shared laughter. Thus, responding with laughter to a preceding laugh is not always affiliative. In talk about troubles it can convey resistance to aligning as a sympathetic troubles-recipient (Holt, in press).

An analysis of teasing by Drew (1987) revealed that laughter by the “victim” occurs as a response in about one third of the collection. Ways of responding can be seen as occupying a continuum, depending on their orientation to the nonserious nature of the tease, from responding seriously to going along with the tease. Thus “laughing along” occupies a midpoint position between nonaffiliative responses and affiliative ones.

Laughter in Extended Sequences

Analysis of responses to improprieties by Jefferson, Sacks, and Schegloff (1987) also showed that laughter can be a midpoint between fully affiliative and nonaffiliative responses. Responses range from disaffiliating from the impropriety at one end to escalation at the other. Focusing on the extended sequence revealed that there can be a progression of responses from initial resistance, to shared laughter, to affiliation (see also Holt, in press).

Holt (2010) shows how shared laughter may contribute to sequences which close down topics. In responding to laughter in a first turn with shared laughter, or with further topical talk, participants may orient to the trajectory of the talk: Shared laughter is recurrently associated with topic closing.

Laughter and Social Context

Analysis has also focused on the relationship between laughter and the social context of its occurrence, mainly in institutional settings. Adelswärd (1989) investigated laughter in Swedish job interviews. She found that there was more mutual laughter in those interviews where the applicant was successful. Thus, she argues that mutual laughter is indicative of rapport and consensus. Lavin and Maynard (2001) drew their data from telephone survey interviews where laughter on the part of researchers is prohibited because it impacts standardization. Some researchers responded with pseudo-laughter or smile voice in order to maintain standardization and an affiliative relationship with coparticipants.

Analysis of laughter in institutional settings has identified a relationship between it and difficult or delicate interactional environments. A study of doctor–patient interaction by Haakana (1999) revealed that patients tend to laugh more than doctors, and they recurrently

laugh alone. The laughter displays the patient's orientation to the environment as delicate when, for example, rejecting a doctor's candidate understanding or directive.

In multiparty assessment meetings in Swedish detention homes, Osvaldsson (2004) found that laughter often occurs in interactionally awkward environments where there has been a series of oppositional turns.

Patterns of laughing and refusing laugh invitations in institutional environments have been seen as arising from the asymmetrical relationships of participants. West (1984) was concerned with the asymmetrical nature of doctor-patient interaction. She saw laughter as an invitation to "come closer." Like Haakana (1999), West found that patients laugh more than doctors, and that they often laugh alone; thus "patients volunteer laughter more readily than doctors, but their invitations to laugh have much lesser likelihood of acceptance than do those of physicians" (p. 120). Vöge (2010) also found a relationship between laughter and the realization of hierarchy during complaint sequences in business meetings. When the complainant is in a subordinate role to the complaine, laughter can be used to contribute toward the implicitness of the complaint as well as seeking alignment and affiliation.

Other aspects of role, membership categorization, identity, and participation frameworks have also been found to be enacted and transformed through laughter. For example, in a business meeting involving participants from several different countries, Markaki, Merlino, Mondala, & Oloff (2010) showed how laughter can reconfigure groups through affiliation and disaffiliation and by making national categories salient.

Conclusion

Thus, analysis of laughter in interaction has revealed that it is orderly, and its use is tightly bound up with lexical elements of turns and sequences. It is certainly not always a reaction to humor, and, in fact, much CA research has focused on the use of laughter where there is nothing manifestly funny about the preceding talk. Reasons for the use of laughter are hard to pin down, but analysis has revealed that it can contribute to the action of turns and sequences. It recurrently occurs within turns, at the end of turns, and as a response to prior talk. Much research has tended to focus on laughter in two-party interaction, but Glenn (1992) has found that the number of participants can make a difference to who laughs first.

A first laugh can invite shared laughter. However, shared laughter is much less common in interaction than solo laughter, and there are many interactional environments where responding affiliatively does not involve reciprocating the laughter. It is clear, however, that laughter (whether in response to a laugh invitation, or as volunteered) can sometimes be affiliative. It can also contribute to the interactional construction of rapport and intimacy. Research on laughter in institutional environments has highlighted its role in contributing to awkward, delicate, or in some other way problematic talk, and has also suggested it may be associated with hierarchical organization, membership categorization, and participation frameworks.

The term "laughter" is commonly tied up with notions of mirth and amusement. Thus, there is a danger that using this term for certain sounds in interaction imports assumptions about its nature that are unwarranted. It also glosses over distinctions between the many different kinds of sounds that are seen as constituting the category. But CA provides an appropriate approach for continuing analysis of the use of these sounds in talk, of how they contribute to sequences, and of potential distinctions between ones that occur in different sequential positions and follow different prosodic patterns.

Conversation Analysis and Learning in Interaction

TIMOTHY KOSCHMANN

Learning as Change in Practice Over Time

As can easily be seen from other entries, learning is a central topic in applied linguistics research. This entry addresses itself to a very basic question: How does one go about studying learning in interaction? There are, of course, many ways to study interaction itself. Conversation analysis (CA) is one approach, one that focuses on the practical details of how talk-in-interaction is organized (Sacks, 1992; Schegloff, 2007). Arguments have been advanced elsewhere pertaining to the benefits of adopting CA methods in applied linguistics research (Firth & Wagner, 1997, 2007; Schegloff, Koshik, Jacoby, & Olsher, 2002; Mori, 2007) and there is a growing body of interesting work that has emerged from that proposal (e.g., Brouwer & Wagner, 2004; He, 2004; Mondada & Pekarek Doehler, 2004; Lee, 2006; Hellermann, 2007; Sahlström, 2009). Schegloff et al. (2002) caution, however, “Since CA research is theoretically and methodologically grounded as a study of publicly observable phenomena, the view of competence it supports is one of situated practices rather than psycholinguistic models of learning processes and knowledge structures” (p. 13). Does CA’s orientation to witnessable practice preclude the study of learning using CA methods? This entry seeks to address this question.

We begin by considering just what it means to learn something. A classic definition of learning in psychology was provided by Hilgard and Bower (1966), who stipulated:

Learning is the process by which an activity originates or is changed through reacting to an encountered situation, provided that the characteristics of the change in activity cannot be explained on the basis of native response tendencies, maturation, or temporary states of the organism (e.g., fatigue, drugs, etc.). (p. 2)

Their definition, a technical one designed to serve as a point of departure for scholarly inquiry, captures several features of our everyday understanding of what we mean when we say someone has “learned” something. As they specify from the outset, “learning” is processual. It is a transitive verb requiring both a subject (“the organism”) and an object (the “activity”). It cannot be detected within an activity itself, but resides instead in the ways that activity is transformed over the course of time. As Hilgard and Bower noted, practices may change for a variety of reasons and not all changes in practice necessarily constitute learning. In any case, to recognize that a change has occurred requires a judgment of regularity. To study learning, therefore, is to plunge into an investigation of regularities.

The Investigation of Regularities

To consider two or more events to belong to a named category (e.g., religious observances, academic lectures, play performances) rests implicitly on judgments of cases being in some

2 CONVERSATION ANALYSIS AND LEARNING IN INTERACTION

sense the “same” for the purposes of analysis. According to Winch (1990) such judgments underlie all research seeking to render accounts of regularities in the social world. He wrote, “A regularity or uniformity is the constant recurrence of the same kind of event on the same kind of occasion; hence statements of uniformities presuppose judgments of identity” (p. 78). Winch asserted that the rules defining identity in social science research are investigation-specific: “To investigate the type of regularity studied in a given type of enquiry is to examine the nature of the rule according to which judgments of identity are made in that enquiry” (p. 78).

Baccus (1986) argued contra Winch that judgments of identity are not solely an investigator’s constructions, but trade upon that investigator’s knowledge as a competent practitioner of the matter under study. Baccus wrote:

[T]he investigator must first have some idea of the internal workings of a social phenomenon (in its naturally available way) before he can go on to make statements about the phenomenon from his point of view as an investigator. He thus must have some practitioner’s knowledge about his object, knowledge which is “unreflective” because it is in natural use by members of the production of the phenomenon. (p. 2)

She argued that rules defining identity are part of the “criteria and concepts” (p. 3) that inhere in the social situations being studied. They are, in this way, internal to the matter being studied. She concluded, “If identity judgments are to be valid and appropriate to some phenomenon, given phenomenal integrity, then the ‘rules’ to which Winch refers are those of everyday social theorizing and investigation is a set of practices which explicitly accommodates these as not only legitimate but as primary operations of investigation” (p. 4).

Studies of learning, however, must go beyond simple investigations of regularities. As mentioned earlier, learning entails change. To ascribe learning, two activities must be sufficiently similar to be recognized as belonging to a common category, but must at the same time be perceived as different in some way. To recognize learning, therefore, requires a “same-but-different” analysis; it requires both judgments of identity *and* dissimilarity. Consider an example of a father and his young child. Suppose before they leave the house each morning they follow a ritual whereby the child seats herself near the door while her father ties her shoes. Their activity is oriented to and produced as a familiar one—they are doing “tying shoes” and they are doing it together. Suppose one morning the father encounters the child at the door, but this time her shoes are already tied! We might reasonably gloss the situation by saying “something had been learned,” but what about this situation represented learning? Learning, from an interactional perspective, is to be found within the embodied methods whereby the participants detect and display changes in the ways their joint activity is organized.

This is a somewhat different treatment of learning than that conventionally employed in the behavioral sciences. It is an ethnomethodologically informed treatment, one that locates the phenomenon not in the subject’s head, but rather in the methodic character of the activities within which the subject participates. To use Garfinkel’s (1967) terminology, learning is a *members’ method* or, perhaps more accurately, learning is the set of members’ methods whereby we display and detect developmental change within our familiar and recurring activities. Recognizing learning in ourselves and others is a natural part of functioning as a competent member of society. Learning is an accountable, public, and locally occasioned process. By this view, interaction does not just provide *evidence of* learning; it is where learning itself is to be found. We might call this learning-in-and-as-interaction. Our task as investigators is not to certify that learning has occurred, for that is a member’s matter, but rather to give an account of just *how* members conduct the investigations into

the regularities that Winch described. What is needed, ultimately, is an investigation into their investigations and into their "everyday social theorizing" (Baccus, 1986, p. 4).

Empirically Grounded Accounts of Action in CA

Having developed in sketch form an alternative framework for thinking about learning, we now turn to the requirements for adequate description in CA. Research in CA rests upon a fundamental distinction between *practice* and *action*. Its task is to give an account of the forms of situated practice that produce recognized categories of social action. Schegloff (1997) cautioned against oversimplifying this relation, suggesting that analysts need "to remain alert to an action-formation resource pool, in which practices, deployed always in some position, can accomplish different actions; and actions can be accomplished through a variety of situated practices" (p. 505). Schegloff (1996) stipulated further that an account of precisely how a practice produces an action must include three elements. A fundamental feature of all CA research is a resolute insistence that any claim or finding must be grounded in what can be heard or seen in the available record. An account, therefore, must offer "a formulation of what action or actions are being accomplished, with compelling exemplification in displays of data and analysis" (1996, p. 172). A second requirement is a "demonstration that the interlocutors in the data being examined have understood the utterances (or other conduct) in question to be possibly doing the proposed action(s) or that they are oriented to that possibility" (p. 172). Building this demonstration requires a close examination of the sequential environment within which an observed practice was produced, particularly any talk or conduct that immediately follows. "This immediately subsequent talk [or conduct], being appropriate to—or even responsive to—what preceded it, ordinarily displays an understanding of what the preceding talk was 'doing'" (p. 173). Attending to participants' displayed relevancies is an important means of keeping the analysis honest. But providing evidence that a practice was understood by participants in a certain way does not yet constitute an adequate account of the practice-action relation. What is still required is "a specification of the methodic basis for the construction, deployment, and recognition of [the] action" (p. 173). An adequate account, therefore, must describe "what about the production of that talk/conduct provided for its recognizability as such an action; that is, what were the methodical, or procedural, or 'practice-d' grounds of its production" (p. 173).

The strategy proposed by Schegloff is one of collecting material exhibits of practice, specifically practices that produce a targeted action. Such collections may draw on a diversity of settings and subjects, possibly sampling across multiple data corpora, using inclusion criteria that are indifferent as to exactly who produced the investigated practices and when. The process is exploratory; it involves "finding out what one is collecting in the process of collecting it" (Schegloff, 1997, p. 502). A compiled collection constitutes a critique-able specification of the practice-action relation. It represents an empirically grounded theory of the action. It serves as something "to which an empirical account of action can be answerable and by which it can be constrained" (Schegloff, 1996, p. 168).

Baccus's "natural use" knowledge of the internal workings of the phenomena under study is accommodated in specific ways in Schegloff's three criteria for producing empirically grounded accounts of action. As he stipulated, the account must specify what sort of action is being performed. Doing so presumes some sort of rule of identity as described by Winch. The account must also demonstrate that participants orient to the observed practices as accomplishing the specified action, that is, that they apply the identity rule in the same way as the analyst. Finally, it must include a description of *how* the specified action provides for its own recognizability. Participants must carry out their own analysis

of their interaction to achieve this recognition. Their methods for analyzing their own conduct become, in CA research, both a resource and a topic. In this way, CA accounts are, like the descriptions of learning-in-and-as-interaction, based upon an investigation of an investigation.

Empirically Grounded Accounts of Learning

Learning, as conventionally construed, seems oddly out of place amongst the “generic problems and practice(d) solutions” (Schegloff, 2006, pp. 71–83) that have traditionally served as the objects of study in CA research. CA concerns itself with the organization of talk-in-interaction. The very notion of “acquiring a language” is seen as incompatible with the basic tenets of CA research (Brouwer & Wagner, 2004; Firth & Wagner, 2007). As He (2004) argued, CA “is not a learning theory and thus is not designed to document language acquisition” p. 579). The incompatibility lies in using CA methods to do something that it is not designed to do—to certify learning conceptualized as an unobservable, occult matter. When learning is conceived of as a public and accountable process, however, this incompatibility disappears. Nonetheless, some accommodations must be made before we will be able to start producing empirically grounded accounts of learning analogous to the kinds of accounts of action proposed by Schegloff.

CA collections, as described by Schegloff (1997), are comprised of material exhibits selected to display the range of practices employed to produce an identified action. To produce an analogous empirically grounded theory about learning, a different sort of collection will be required. Where CA collections are comprised of simple practices, *learning collections* will consist of one or more ordered sets each representing a trajectory of practice observed over time. This will necessitate new forms of data gathering. Whereas a researcher constructing a traditional CA collection may be indifferent as to *who* produced a particular practice and *when*, such information is essential when attempting to reconstruct how an action developed over time. To start to build learning collections, therefore, we will need new sorts of data sets, data sets that track individual participants over extended periods of time. Fortunately, some language learning researchers have already started to build such corpora. Wootton (1997), for example, constructed a longitudinal corpus to study how a single infant came to perform certain actions (e.g., making requests) over time. Others have constructed corpora that allow for the study of changing practices among adults as they begin to interact within a second language (e.g., Brouwer & Wagner, 2004; Mondada, & Pekarek Doehler, 2004; Hellermann, 2007).

An important thrust of 20th-century philosophy was to find ways of dissolving the dualism of mind and world. Studying learning-in-and-as-interaction provides us with a means of conceptualizing and investigating learning as a worldly matter. It enables us to understand learning as a methodic and “practice-d” matter (to paraphrase Schegloff). It provides a means of better understanding how participants in interaction conduct investigations into the changes in practice that serve as the basis for their avowals and ascriptions of learning. Learning collections constitute empirical theories about just how such investigations are accomplished. This represents not so much a departure from the traditional program of CA research as its logical extension. CA collections of the sort described by Schegloff will supply the categories of action upon which learning collections will eventually be constructed. By the same token, empirical work on learning-in-and-as-interaction will open the door to a whole new line of inquiry in CA, inquiry into how actions develop over time. It represents a significant direction for future research.

Conversation Analysis and Lingua Franca

ALAN FIRTH

This entry outlines an emerging body of research that deploys conversation analytic (CA) methodology and its theoretical underpinnings to explicate the micro-details of talk and social interaction between people who communicate in a lingua franca (LF). An LF may be defined as a “contact” or “vehicular” language used by people who do not share a first language (L1) and who are not native speakers (NSs) or L1 speakers of the language being deployed. An example of an encounter where the language used may be characterized as an LF is an L1 speaker of Spanish interacting with an L1 speaker of Mandarin Chinese *in French*—in which case French is the LF. As this example indicates, a language’s characterization as an LF is determined not by the characteristics of the linguistic code but by the relationship of its speakers to the language being deployed. The term “LF” does not describe or imply any particular level of speaker proficiency, linguistic sophistication, or communicative competence. Any language can function as an LF, although it is widely accepted that English has, in recent decades, become the world’s preeminent LF (e.g. Jenkins, 2006). This is reflected in the fact that the bulk of empirical research has concentrated on how English has been used in its guise as an LF.

The Genesis of CA and LF

During the 1960s and early 1970s—that is, the first decade or so of its emergence as a discipline—CA research overwhelmingly focused on L1 speakers (of English) in the predominantly English-speaking communities in the United States and, subsequently, the United Kingdom. This focus in terms of data may have been largely incidental, as English produced by L1 speakers was, presumably, the speech community most conspicuously accessible (and familiar) to conversation analysts. If second, third, or *n*th language speakers of English were participants in the data corpora collected by the earliest CA researchers, the notion of “other language” speakers remained unexamined. Thus, as Firth (1996, p. 238) notes in his overview of the data collected in the earliest CA research: “a picture emerges of an enterprise that [demonstrated] a remarkably consistent though restricted interest in the talk of ‘normal’ *adults* who are members of the *same culture* and who share and use the *same native language*—in the majority of cases the English language.”

Accessibility of data type might not be the only factor that accounted for CA’s apparent initial lack of interest in interactions involving persons who were not L1 speakers of English, however. The “working assumption” of a community-wide shared competence in and knowledge of language is viewed, in CA, as a resource for both participants and conversation analysts alike for, as Sacks (1995, p. 116 [Lecture 14, 1964]) puts it: “we [professional analysts] can use that information which we have as members of the same society that these . . . people are in.” This “information,” taken to be accessible by dint of co-membership of the lingua-cultural community, enabled Sacks and his colleagues to recognize phenomena as “ordinary,” “canonical,” or “anomalous,” and to make “intuitively plain observations” (Jefferson & Schenkein, 1978, p. 170, n. 10) on the collected data. However,

as Firth (1996) suggests, when analyzing LF interactions, the analyst's intuitions may be less reliable than when analyzing data involving people who may be taken to share—with the analyst—linguistic and cultural membership. This is because LF interactions involve speakers from diverse lingua-cultural backgrounds, whose linguistic proficiencies might vary considerably. This factor may in part account for the relative dearth of early CA research on talk that does not exclusively involve NSs.

One notable exception to this pattern of data-type uniformity was Jordan and Fuller's (1975) much-overlooked article "On the Non-Fatal Nature of Trouble: Sense-Making and Trouble-Managing in Lingua Franca Talk." This was the first publication deploying CA methodology to examine LF interactions. The authors' observations are informed by the ethnomethodological precept—one which fundamentally underpins CA—that social interaction is *achieved* and *accomplished* as and in a conjoint and contingent dialogical process. Indeed, one might argue that ethnomethodology and CA can be properly seen as closely related paradigms whose primary goals are to explicate, and by so doing celebrate, the achieved character of social interaction. This theoretical point of departure doubtless allowed Jordan and Fuller (1975) to highlight the "non-fatality" of communicative perturbations evident in the forms of talk under analysis—a prescient raising of a recurring theme in subsequent CA-LF research.

This thematic emphasis contrasted sharply with contemporaneous applied linguistic research, not informed by either ethnomethodology or CA, on so-called "non-native-speaker–non-native-speaker" (NNS–NNS) or "L2-learner–L2-learner" discourse. This research is overwhelmingly "deficit-oriented" (Firth & Wagner, 1997), in that it emphasizes the frequency and gravity of linguistic and pragmatic "errors" in NNS/second language (L2) learner talk, the overall communicative "limitations" seen to characterize such talk, and the need to draw evaluative comparisons with the so-called "target language" of NSs.

The Emergence of a CA-LF Paradigm

Despite the publication of Jordan and Fuller's (1975) groundbreaking study, it was not until the early-to-mid-1990s that a nascent research paradigm of *CA of LF interactions* began to materialize. This occurred with Firth's (1990, 1996) and Firth and Wagner's (1997) applied linguistic research, which argued for the need to redress the prevailing "deficit orientation" to NNS/L2 learner discourse. This could be achieved, Firth (1990) proposed, in two combined ways: first by replacing the terms "NNS–NNS" or "L2-learner–L2-learner interactions" with the term *LF interactions*, and second by adopting CA's method and concomitant theories (of language, context, competence, etc.) in analyzing such data.

Adopting the term "LF" instead of "NNS," "L2-learner," or "L2-speaker" was more than a cosmetic change. What it does, Firth (1990, 2009) argued, in both highlighting and eschewing the negative connotations of *non-native* and the hierarchical and inferiority connotations of *second language speaker*, while also questioning the relevance of "L2 learner," is to signal a change in theoretical and even ideological stance: from deficit to achievement, from failure to accomplishment, from prejudiced description to unprejudiced description (Firth, 1996). Although by no means viewed as a conceptual or theoretical panacea, "LF" was preferred because, it was argued, it carries less monolingual and NS-centric baggage than the prevailing terminologies (Firth & Wagner, 2007; Firth, 2009).

Similarly, because CA's theoretical foundations are ethnomethodological, this entails the conversation analyst adopting an *emic* (i.e. participant's) perspective on analytical relevancies (Schegloff, 1992), viewing the nature of context and social identities as locally accomplished rather than given or analyst-defined, and giving analytical primacy to uncovering interactional achievement and accomplishment rather than failure and deficit. Firth (1990, 1996,

2009) and Firth and Wagner (1997; 2007) argue that such analytical procedures and theoretical standpoints permit a kind of methodological and theoretical “liberation” for applied linguists in general and second language acquisition (SLA) researchers in particular—scholars who have traditionally focused on language produced by persons who are not NSs of the language being deployed. The “liberation” involves finding alternative ways of conceptualizing the NNS—namely as an agent who is not ipso facto communicatively handicapped by his or her L2 speaker status and who is not ipso facto an “L2 learner” simply because he or she is using an L2.

CA-LF Research

Since the early 1990s there has been a steadily growing amount of empirical research undertaken on discursive interaction in encounters where an LF has been deployed—most often in situations where English is the LF. This research has in large measure been CA in its broad methodological and theoretical orientation, and has sought to reveal and explicate, through detailed transcript analyses, interactional competencies and socially managed patterns of talk-based behavior. Collectively, the research is underpinned by a motivation to describe social interaction without recourse to a “deficit” ideology characteristic of SLA/L2 studies. And, in that CA-LF research has focused for the most part on social settings that are not overtly “educational,” it provides an empirical alternative to L2 researchers’ preoccupations with persons interacting (as “learners”) in L2 classrooms (Wagner, 2004).

CA-informed research into English as an LF (“ELF”) includes Firth’s studies of international commodity traders communicating by telephone (e.g. Firth, 1990, 1996, 2009); Gramkow Andersen (2001) on telephone communications between university administrators; Haegeman (2002) on business meetings; Wagner and Firth (1997) on sales talk; House (2002), Lesznyak (2004), Meierkord (2005), and Kaur (2010) on international student conversations; Jenks (2009) on Skypecast interactions (voice-based chatrooms); and Mauranen (2009) on academic (university) interactions.

Findings reveal an interactional terrain characterized by instances of communicative robustness; interactional deftness, resourcefulness, and adroitness; and a high degree of collaboration and cooperation—despite obvious variations in the participants’ linguistic, cultural, and pragmatic knowledge. Thus far, scholars have been circumspect in positing fundamental differences in interactional patterns and linguistic features between L1 speakers and LF speakers of the same language. What appears to be evident, however, is perhaps a greater preponderance of certain forms, features, and interactional strategies in LF interactions, compared with L1 interactions in the same language. Firth (1996), for example, reveals that a prominent feature of the LF interactions he examined was how participants implicitly engage in what he termed “make-it-normal” and “let-it-pass” procedures, enabling them to imbue the interaction with an appearance of “ordinariness”—in the face of ostensibly “extraordinary” linguistic/discursive behavior. Gramkow Andersen (2001), Lesznyak (2004), Kaur (2010), and Mauranen (2009) uncover a range of accommodatory behaviors—such as rephrasing, repetition, slowed enunciation, and code mixing and code switching—as participants calibrate their conversational contributions in order to retain an appearance of “fluency” and meaningfulness. Kaur (2010) also revealed how the interactants in her study restricted the conversational topics to those deemed culturally “safe.”

A key theme in these researchers’ work is highlighting participants’ orientations to difference, particularly in cultural and linguistic knowledge, as this is manifest in the skilled deployment of a range of *preemptive* or *proactive* strategies—all of which serve to circumvent or minimize the risk of miscommunication and, perhaps more importantly,

the need to avoid topicalizing communicative difficulty within the interaction. Further, in the LF interactional research thus far undertaken, there appears to be a collective orientation to resisting behaving in ways that may result in being viewed as an “L2 learner” (Firth, 2009).

Clearly, though, such findings are a characteristic of the data types and settings hitherto subjected to analysis, and influenced by the interactional goals of the participants, their social relations, and the relatively minor variations in linguistic proficiency observable in the LF interactions examined so far. Analyses of data from a significantly wider variety of social settings, involving participants with greater variation in proficiency in the LF, would appear to be urgently required (Seidlhofer, 2001). With a continued expansion along these lines, research within the CA-LF paradigm will doubtless become increasingly significant within the fields of discourse studies, L2 research, sociolinguistics, intercultural communication, and CA.

Conversation Analysis and Meetings

BIRTE ASMUß

Meetings have traditionally been dealt with as preplanned, ordered organizational events, in line with Schwartzman's definition of a meeting as "a communicative event involving three or more people who agree to assemble for a purpose ostensibly related to the functioning of an organization or a group" (1989, p. 7). As a response to this rather functionalistic view, an increased focus on interaction in meetings has developed in recent years. Cooren (2007) sees a move from the "interpretive turn" in the 1980s and the "discursive turn" in the 1990s toward the "interactional turn" (p. xii). The "interactional turn" is characterized by the increasing focus on studying and understanding the details of complex workplace interactions, and is methodologically mainly based on conversation analysis (CA).

The advantages of a CA approach to the study of workplace interactions such as meetings are based on CA's focus on actions as collaborative achievements. For meetings this means that instead of being seen as events characterized by the fixed roles of the organizational participants, they are seen as the interactional accomplishments of all participants. CA makes it possible to show "how conversations contribute to the production of organizational roles, for example, superior-subordinates, labor-management, and interviewers-applicants" (Putnam & Fairhurst, 2001, p. 86). It is the reciprocal, local, and continuously ongoing negotiation between all meeting participants that constructs and reconstructs meeting characteristics such as being formal, informal, more or less goal-oriented, and so on (Drew & Sorjonen, 1997). Hence, meetings are crucial events for the emergence of organizations, as it is through such institutional conversations that organizations arise.

The view on the "emergent organization" is central to a basic notion of CA, namely the role of context (Heritage, 1984). Through their way of orienting to the conversational encounter as being a meeting, participants create a context for the meeting and at the same time are influenced by the organizational context in which it takes place.

One of the central CA studies on meetings is Boden's *The Business of Talk* (1994). Here she points out the importance of seeing meetings as local accomplishments dominated by talk: "Talk and its turn-by-turn sequential accomplishment are what meetings are about, however many memos, minutes or reports may be written before, after or in reference to the event" (Boden, 1994, p. 82). This does not mean that events outside the actual meeting are seen as irrelevant. From a CA perspective, events prior to meetings such as memos, minutes, phone calls, and earlier meetings are seen as resources for the actual meeting talk. Hence, instead of attributing to these events a priori a fixed role for the meeting, their meaning is allocated locally in the meeting and negotiated recurrently by all meeting participants.

CA studies of meetings have dealt with a variety of different topics (Asmuß & Svennevig, 2009). One central topic is the question of meeting management and meeting leadership (Pomerantz & Denvir, 2007; Clifton, 2009; Nielsen, 2009), and related to that, questions of asymmetry and hierarchy in meetings (Huisman, 2001; Clifton, 2006). Studies show how middle managers do leadership by collaborating closely with employees in interpreting and defining goals and contextualizing employee actions (Nielsen, 2009) and how asymmetry in meeting talk is interactionally achieved by the use of formulations (Clifton, 2006).

2 CONVERSATION ANALYSIS AND MEETINGS

Another central question deals with meeting openings and closings (Boden, 1994; Arminen, 2001; Kangasharju & Nikko, 2009). It has been shown, for example, that meeting openings and closings are fine-grained, well-coordinated activities which mark the boundaries of more informal pre- and post-meeting talk. The study of agreement and alignment in meeting interaction has been another area of major interest (Kangasharju, 2002; Asmuß, 2007). Here it has become apparent that alliances in meetings can be built through collaborative completions, repetitions of directly prior items, and embodied actions such as head shakes (Kangasharju, 2002) and that the way requests are made reflects the degree of entitlement to actually make them (Asmuß, 2007).

CA has traditionally focused on verbal aspects of interaction. As a response to this monomodal focus, in recent years a range of CA studies have developed that focus more on meeting interaction as embodied action. One of the new lines of research is the field of “microethnography” or “video-based ethnography” (LeBaron, 2008), which is informed by ethnographic approaches to workplace studies. Apart from taking the complexity of workplace interaction seriously by including both the verbal and the embodied interaction, this line of research relies to a greater degree than traditional CA work on single case analysis, where the aim is to show in detail the sequential disposition of longer stretches of interaction instead of building collections of specific actions. Another recent development which reflects on the different modalities that are at stake when talking about meeting interaction is the focus on multimodality (Sidnell & Stivers, 2005). Especially within the field of meeting interaction, more and more studies deal with the way the multimodal environment influences different kinds of meeting interaction in the form of resources and restrictions (Mondada, 2009; Svennevig, 2012).

Within the last decade, the analysis of meeting interaction from a CA perspective has attracted major attention within a new, rapidly evolving field of management studies, namely strategy-as-practice (Golsorkhi, Rouleau, Seidl, & Vaara, 2010). Instead of seeing organizational strategy as the result of an isolated managerial task, strategy-as-practice opens up a view on strategy as an ongoing organizational process which includes all organizational members. A number of studies address the question of how strategy is implemented, negotiated, and interpreted through different kinds of meeting talk.

Conversation Analysis and Membership Categories

DENNIS DAY

Membership categorization analysis (MCA) deals primarily with the way we use categories to make sense of and for each other in social interaction. As such, it is one means of explicating the practically oriented, commonsensical, and cultural reasoning of people as they go about their social lives. In particular it focuses on the recognizability of people as certain sorts of people or, more specifically, people as certain sorts of members of society, and how this recognizability is a resource for members in their dealings with each other. And as one of the primary ways in which we “deal” with each other is through language, MCA is often brought to bear on the analysis of how people use language in situations of everyday life.

As with other strands of ethnomethodology and conversation analysis (CA), with their focus on the everyday methods by which we live our lives, there is a special way to understand what is meant by “analysis.” When we use the term “MCA,” we are here of course referring to the ways in which we, as analysts, explicate some empirical material; however, we can also use the term as a gloss for what the people in our empirical material are doing—they are categorizing each other as certain sorts of members of society. Thus what we, as analysts, are doing is simply bringing to light members’ own analyses. MCA should thus not be thought of as, for example a theory of social categorization that is applied to some empirical materials to test its predictability, but rather as the explication of people’s own resources for social life.

MCA has its beginnings in the work of Harvey Sacks (1972a, 1972b, 1992), who became interested in the way in which categorizations rely on social categories, such as policeman, mother, deviant, and how these and associated social categories might be organized into collections, known as membership categorization devices (MCDs).

My attention shall be exclusively limited to those categories in the language in terms of which *persons* may be classified. For example, the categories: “male,” “teacher,” “first baseman,” “professional,” “Negro,” etc., are the sort I shall be dealing with. Frequently such “membership” categories are organized, by persons of the society using them, into what I shall call “collections of membership categories,” categories that members of society feel “go together.” . . . They are not constructed merely as aids to my analysis; whether or not a particular category is a member of a particular collection is, in each and every case, a matter to be decided empirically. (Sacks, 1966, pp. 15–16; original emphasis; cited by Jayyusi, 1984, p. 212)

The central elements in the use of social categories, according to Sacks, are MCDs and a set of “rules of application.” Rules of application match categories from a device to individuals or collections of individuals. Of particular interest are the “consistency rule” and its corollary, the “hearer’s maxim.” The consistency rule states, roughly, that if a category from an MCD is used to categorize a member of a particular population, then all other members may be categorized with categories from that device. One may view the consistency rule as applying to the production of a categorization such that speakers may

co-select categories from within the same device. The hearer's side of the consistency rule is termed a "hearer's maxim": "if two or more categories are used to categorize two or more members of some population, and those categories can be heard as categories from the same collection, then: hear them that way" (Sacks, 1992, p. 221). Furthermore, such categories may provide for inferences concerning typical activities of their incumbents. Such activities are referred to as being category-bound (Sacks, 1992).

Of special interest to Sacks and those who have followed him has been the following problem: Given that a person may be described "correctly" in an infinite number of ways on a given occasion, what are the principles of a "proper" description? One such principle by which a description becomes proper is through its being heard as relevant in falling under an MCD relevant to the talk at hand.

The classic example from Sacks, derived somewhat atypically from a book of stories by children, is how we understand the expression "The baby cried, the mommy picked it up." Sacks contends, and the reader is encouraged to try this on their own, that we hear the "mommy" as the "baby's mommy." The basic idea is that if we can hear the rendering of the categories "mommy" and "baby" as belonging to the device "members of a family," then we hear them that way. We may say that picking up their babies is a category-bound activity of mommies, something mommies are expected to do. Thus when offered a description of some mommy picking up some baby, we infer they are members of the same family.

MCA, along with the analysis of turn sequencing and recipient design provided by CA, provides a powerful analytic tool-kit with which relationships between interactants can be understood (Sacks, 1992; Antaki & Widdicombe, 1998; Hester & Eglin, 1997). With regard to MCA analysis of spoken interaction, categorical analysis, in fact, is necessarily carried out in parallel with sequential analysis. Most MCA practitioners would also claim the converse—sequential (CA) analysis by necessity implies categorical analysis. There has been some debate on the relationship between CA, with its focus on sequentiality, and MCA. Details concerning this can be found in Watson (1997), Housley and Fitzgerald (2002), Wowk and Carlin (2004), and Schegloff (2007).

Moreover, MCA has been further developed since the early work by Sacks, both conceptually and empirically. Jayyusi (1984, 1991) brought out the moral and normative character of categories and categorization. Recall from the mommy and baby example above that we expect mommies to pick up babies. It is not far from that to suggest that as we expect them to do so, they *should* do so, and in this way issues of normality and morality can be seen to come into play. For more empirical work in this vein, see for example Antaki, Biazzi, Nissen, and Wagner (2008), Arminen (1996), Baker (1997), Eglin and Hester (1999), Heritage and Lindström (1998), Hutchby (2001), and Stokoe (2003). The second major conceptual development within MCA has been Watson's (1978) extension of the notion of category-bound activities to the more general notion of category-bound predicates. Thus not only activities, or actions, may be bound to categories but also a wide range of characteristics, essentially whatever can be "properly" predicated of an incumbent to the category. Not only can we hear mommies as "picking up babies," but also as being of a certain age, of having certain kinds of knowledge, and so forth. The notion of category-bound predicates has become quite general in MCA research. It is important to point out, however, that with the moral or normative implicativeness of both categories and category predicates, their applicability is always bound to concrete situations of categorization and should not be thought of as "context-free" properties of linguistic expressions.

Belonging to the "family" of ethnomethodology and CA, MCA is rarely an object of abstract theorizing. Rather, in discussion of it, data, consisting of as close a record as possible of human interaction, are always in the foreground. MCA may work with transcripts of spoken interaction as CA does, but also with texts as well as detailed ethnographic

documentation of settings and the people in them. Let us then have a look at a bit of spoken interaction to get sense of how MCA works. The data come from a video recording of a group of university students engaged in a “project group meeting,” that is, a group with the task of conducting a study and writing a report by the end of term. At our point of entry in the transcript, they are making a list of the tasks they have before them. Our focus will be on the categories they use, but also on where and how they are used in the turn-by-turn construction of the interaction.

(1)

- 01 ERN: which days days [we have is it two or what]
 02 LOU: [but this is my eat pasta]week
 03 ERN: °your what?°
 04 LOU: °I have to eat pasta all week°
 05 ERN: °why that°
 06 PET: you gotta me kiddin me (.) you're not on one of
 07 those stupid diets are you?
 08 LOU: uh no no no I'm must a I'm just er (.)
 09 PET: you [broke]
 10 ERN: [did you] lose a bet?
 11 LOU: just broke
 12 PET: yeah ha ha [ha HA HA HA gid]dy e giddy e giddy me::?
 13 LOU: [that's my diet]
 14 ERN: [(xx)]
 15 PET: [which] brings us to another subject (1) shouldn't
 16 we arrange like to do something fun with each other
 17 again soon?

In line 1 ERN is asking which days a particular task is to take place. LOU begins a turn at line 2 where ERN's ongoing inquiry may finish, and in overlap with ERN notes a particular feature of the week which ERN's inquiry concerns, that it is her eat pasta week. LOU succeeds in gaining the turn after the repair sequence which follows, and thus her contribution becomes the focus of continuing activity. LOU's contribution at line 2 is subjected to repair, initiated by ERN in line 3, to which LOU responds by reformulating her attribution of the week in question in line 4. This then is subjected to an inquiry by ERN as to the reason for the attribution of why LOU has to eat pasta all that week. Thus we get the sense that whereas the repair sequence in lines 3–4 may concern a mishearing of what LOU has said, the inquiry beginning at line 5 concerns rather how the eat pasta week is to be coupled with LOU. In MCA terms we can say it like this: What sort of category is LOU a member of such that “eat pasta week” is a proper predicate? What follows are three candidate accounts posed as inquiries for why LOU will have a pasta week? The answer to this will depend on her reasons for having an eat pasta week. PET inquires in “teasing” fashion at lines 6–7 if she's on one of those stupid diets, PET inquires if LOU is broke, and ERN inquires if LOU has lost a bet. LOU denies being on a diet at line 8, does not attend to the question of losing a bet, and answers affirmatively that she's just broke in line 11. Thus LOU “uncouples” a connection between herself and being on a diet, much less one of those stupid ones.

PET carries on in line 12, nonetheless, rejecting LOU's account of her pasta week as being a matter of being broke with what sounds like an ironic *yeah*, laughter tokens, and repeating part of his initial contribution at line 6. His *giddy e* can be understood as *kidding me*. LOU continues her turn in line 11, in overlap with PET, with the clause in line 13 *that's my diet*, which we can hear then as proposing that being broke is the only reason for her particular diet of the week. Thus her diet, as it were, should be understood simply as the

food she is to eat that week, that is, in another sense of the word diet, and not a particular diet, that is, one for losing weight. LOU is thus not heard as the type of person who would go on a stupid diet, as being an incumbent of a category with that possible predicate. Instead, she makes herself out to be an incumbent to the category of people whose diets, in the sense of “food intake,” are adjusted to their dire economic situation. Using our members’ knowledge of people like LOU, ERN, and PET in this setting, the category of “poor student” does not seem too far off.

We may also reflect upon what LOU avoids by her answers to the three inquiries. She does not respond to the “bet” inquiry, but she does to the “stupid diets” one. Our question then is: What sort of category might the action “be on a stupid diet” bind in this setting? One alternative might be to turn to the Sacksian notion of “omni-relevant” categories, and in this case “sex” seems most intuitive. Thus, we might propose that LOU has deflected a “gendered” MCD, whereby being on a stupid diet might be coupled with “woman,” opting instead for an MCD organizing “people with little money,” such as “students.”

The idea that categories are important in human life is not new, especially within studies of language, where linguists have long pondered the relation of categories to thought and language. MCA takes a different tack, focusing instead on categories and social practice, a notion summed up nicely by Derek Edwards in the title of his article from 1991, “Categories are for talking.”

Conversation Analysis and Multimodality

KRISTIAN MORTENSEN

Introduction

In recent years, the number of conversation analysis (CA) publications and presentations that incorporate information about participants' bodily conduct has increased dramatically (for a recent review see Stivers & Sidnell, 2005). Ranging from loose glosses of participants' movements to detailed transcription and systematic sequential analysis of gaze, gesture, and other visual information (most often) in relation to talk, they all address the importance of visual aspects *for* participants *in* social interaction; that is, social interaction is intrinsically *multimodal*. Although "mainstream" CA from its outset was primarily interested in the organization of *talk-in-interaction*, the inclusion of bodily conduct is not entirely new to CA. For instance, Sacks, Schegloff, and Jefferson (1974, p. 717) mention the role of gaze as a device for allocating turns between participants. Additionally, several researchers have been focusing on the interplay between verbal and visual aspects of interaction from early on (e.g., Goodwin, 1981; Heath, 1986). Today video data largely serve as the preferred data type in situations in which participants have visual access to one another, but analysis of the inclusion of bodily conduct in the *systematic* construction of social practices is relatively new. The aim of this entry is to provide a brief overview of research conducted within a CA approach to multimodality, and to sketch the major methodological challenges in this endeavor, including:

1. describing which aspects, among talk, body movements, and physical artifacts in the surroundings, are treated by the participants as *relevant* to the ongoing social actions that the participants are engaged in;
2. the sequential or serial position, or both, in which verbal and visual resources occur; and
3. the social practice that the sequential and serial coordination of different modes accomplishes.

The inclusion of visual aspects in and for interaction is far from limited to CA research, but has strong roots within (in particular) social sciences and human-computer interaction (HCI): Psychology and psycholinguistics have a long tradition of studying in particular gesture's relation to talk as a window on the mind (e.g., McNeill, 1992). Sociology and anthropology have studied the bodily behavior of individuals and social groups in various settings and cultural groups (e.g., Goffman, 1963). HCI adopts linguistic or anthropological approaches, or both, in analyzing the embodied ways in which humans engage and interact with and around various types of technology and computer software (e.g., Heath & Luff, 2000; Suchman, 2007), often with the aim of guiding IT designers in shaping new user-based technologies. Recently, multimodality has also been used as an umbrella term for a range of heterogeneous approaches at the intersection of linguistics, semiotics, visual studies, and discourse and interactional analysis (Kress, Jewitt, Ogborn, & Tsatsarelis, 2001; Norris,

2004; Jewitt, 2009). Of particular relevance here is *multimodal interactional analysis*, which aims at analyzing the interdependence of *embodied modes* (like talk, gesture, and posture) and *disembodied modes* (like background music, layout, text, and images; Norris, 2004).

A CA approach to multimodality, however, differs from the latter approach in two fundamental ways. (a) Although the aim of multimodal interactional analysis is to describe the interrelation of different modes, it starts by providing a detailed analysis of each semiotic field in its own right—as a grammar of gesture, gaze, and so forth. CA’s approach to multimodality, on the other hand, does not describe each mode independently, but as an interplay between various semiotic fields. (b) Multimodal interactional analysis *assumes* that everything is relevant to and affects the ongoing interaction, but does not adopt an *emic* approach as does CA. In her introductory monograph to the field, Norris writes: “In multimodal interactional analysis we are *only* concerned with what individuals express and others react to” (Norris, 2004, p. 4, emphasis in original). Although this resembles the aim of CA, it does not necessarily include a *social* interactional perspective in the analysis. For instance, Norris describes how individuals incorporate the rhythm of background music in the way they walk (Norris, 2004, pp. 41–4). Although this is, indeed, an interesting observation, the focus is quite different from CA’s scientific aim, namely to describe recurrent practices of social interactional phenomena. There is thus a crucial difference between *assuming* that everything is relevant, and CA’s claim that everything *might* be relevant, but is not necessarily *made* relevant by the participants.

Multiple “Modes”?

Multimodal analysis, from a CA perspective, attempts to describe how talk, visual resources (predominantly gesture, gaze and body posture), the use of physical artifacts in the participants’ surroundings, and the surroundings themselves are *jointly* used to perform coherent social action. Rather than regarding these different semiotic fields as contextualizing talk, it is precisely the combination of them, sequentially as well as serially, that produces a specific social action. In this light, it is somewhat misleading to talk about *multimodality* since participants themselves cannot be seen to orient to the modes as being independent from one another. The term “multimodality” is therefore not to be taken as an *emic* category, but as an analytical one, and talk, or any other modality for that matter, cannot a priori be given analytic priority. Although the aim is not to describe a “grammar” of, for instance, gestures, the different modes provide different semiotic properties (Enfield, 2005, p. 52): Where verbal talk is dominated by a high degree of symbolic meaning, the visual modalities are (primarily) indexical, that is, they are made meaningful in and through the sequential context in which they are embedded. Without assigning a more prominent status to “talk,” Goodwin notes that “to see a gesture as a meaningful sign . . . a hearer must first use the talk that accompanies it to find a relevant sense for the speaker’s waving arm and then synthesize into a larger whole a succession of different hand movements that appear and disappear through time” (2002, p. 33). Goodwin talks about “different *kinds* of sign, with each kind getting crucial aspects of its structure from the medium used to construct it” (2002, p. 29, emphasis added). At any point in interaction, certain semiotic fields are relevant to the ongoing action and are oriented to by the participants. As the interaction unfolds, some semiotic fields may lose their relevance and others may come in focus as part of the contingent progression of interaction (Goodwin, 2000a).

A methodological challenge to this aim is to connect the interplay of verbal and visual resources in *building collections of social practices*. This implies documenting how the visual resources perform *interactional contributions*, that is, that (a) they are used *systematically* in interaction and (b) they perform, in a specific sequential context of surrounding verbal

and visual actions, *recognizable social actions*. As the analyst includes a whole range of resources, the more complex (for the analyst, that is, *not* necessarily for the participants) it becomes to find other instances of the same social practice. Most studies, therefore, focus either on a single case analysis and the intertwined complexity of the various resources employed, or on a single visual resource in relation to talk to perform a specific social practice. Below follows a brief overview of the CA research that has been conducted in the different semiotic fields. Although this may appear slightly contradictory, the aim is not to give the impression that each mode is analyzed independently. Rather, the aim is on the one hand to provide a comprehensive overview of multimodal CA research to readers who may not be familiar with, for instance, gesture studies from other research traditions, and on the other hand to present (or rather sketch) research on interactional functions that may be specific to each semiotic field.

Talk

Since the 1960s, CA has studied the organization of social practices in talk-in-interaction. Ranging from descriptions of the organizations through which social actions, and more generally *intersubjectivity*, are accomplished, such as turn-taking organization, sequence organization, and the organization of repair, to specific social actions, such as doing assessments and word searches, CA has documented the co-constructed nature of talk that is intrinsically bound to, and shaped by, the immediate sequential surroundings.

Besides syntactical and lexical dimensions of talk, intonation and prosody are part of the vocal modality. For instance, in relation to turn-taking organization, coparticipants rely on the speaker's intonation in projecting points of possible completion of the ongoing turn construction unit (TCU), although the importance of grammar and intonation in the projection of possible TCU completion is subject to a continuous debate (see, e.g., de Ruiter, Mitterer, & Enfield, 2006). Additionally, in a range of studies Goodwin (e.g., 2000b) shows how a man with severe aphasia (he is only able to pronounce the words *yes*, *no*, and *and*) uses intonation, in coordination with visual modalities, to be a competent "speaker" despite grammatical and lexical limitations.

Verbal talk still serves as the "anchor point" in much CA/multimodal research, although this does not mean that talk is, *a priori*, given analytic priority. The linear temporality of talk makes it a reliable baseline, in relation to which visual modes are temporally organized, when it comes to transcribing multimodal interaction. However, in situations in which verbal talk is (either entirely or partially) absent, such as sign language, transcribing constitutes a practical as well as a methodological challenge. Notions such as pauses and gaps refer exclusively to an absence of *verbal* contributions to the interaction rather than an absence of *action* (Schmitt, 2004). Indeed, (verbal) pauses are often filled with relevant meaningful activities in and through participants' bodily conduct. In this way, multimodality turns the focus from turns-at-talk, in "classic" CA, toward the construction of *action* as the basic unit of analysis. This, inherently, includes a discussion of the applicability of the generally talk-based CA terminology.

Gaze

A large number of studies, from early on in CA's beginning, has documented the role of gaze as displaying the attention of the coparticipant(s) toward the current speaker. Goodwin's groundbreaking (1981) study on the organization of gaze in interaction shows how the recipient's gaze affects the linguistic progression of the speaker's turn-at-talk. He shows how a speaker modifies their turn beginning via pauses, hesitations, and restarts to attract and secure the recipient's gaze, and how recipients remove their gaze toward

the (projected) end of the speaker's turn. In this way, the recipient's gaze plays a role not only for the emergent grammatical construction, but also for the turn-taking organization. Similarly, the speakers' gaze is continuously used to display a shared attention, for instance when manipulating physical artifacts. The action of "seeing" is in this way embedded within the ongoing interactional activity, and plays a crucial role in establishing and maintaining participation frameworks out of which social actions can emerge. Gaze has primarily been described as a recipient activity and has been related to a range of social practices such as receipt tokens, affiliation, and stance display.

Gesture

Gesture and its relation to talk has probably been most extensively studied within psychology, in particular with respect to what the coordination of gesture and talk reveal about inner mental processes. For instance, McNeill (1992) describes how a gesture consists of three phases—preparation, stroke, and retraction—and thus provides a "syntactic description" of gestures. Although similar descriptions have been made within an interactional perspective (Sacks & Schegloff, 1975/2002), the analytic focus lies on the interactional function(s) that are accomplished. Schegloff (1984) shows how ("iconic") gestures precede (and are often terminated before) the lexical affiliate, and thus how they may affect the projection of upcoming talk. Mondada (2007) shows how gestures are systematically used as a way of projecting incipient speakership, and how they can even "interrupt" the ongoing (verbal) turn-at-talk. Similarly, Streeck and Hartge (1992) show how a pre-speech gesture can be "interrupted" by the coparticipant. Although the number of systematic analyses of gesture's interactional properties is still limited it is obvious that gesture, besides its referential properties, plays an integrated part in the basic "machinery," including turn taking, through which intersubjectivity is (co-)constructed.

Bodies and Body Posture

An important interactional function of the human body is to display the level of engagement in interaction. The majority of CA research on body movement and posture is built on Adam Kendon's (e.g., 1990) notion of the *transactional segment*. This refers to the physical space in front of a person, through which participants display their level of engagement in the interaction and understand that of the coparticipants. In this way, the participants create a participation framework, around which they co-organize their actions. Kendon divides the human body into three hierarchically organized segments: the lower body, the torso, and the head (including eyes), which are able to twist around the same vertical axis. Whereas the lower body is the most static part of the body and displays the participant's enduring focus of engagement, the torso and head are more flexible and can, whenever not "facing" the same way as the lower body, display an immediate focus of attention. For instance, when seated in a cinema the lower part of the body would normally be facing the screen (in and through the physical arrangement of the chairs, which again affords and constrains the possibilities for social interaction), and thus facilitate a somewhat relaxed *home position* (Sacks & Schegloff, 1975/2002) with the entire body facing the screen. However, it is possible to twist one's head or torso toward the neighbor (or the guy talking on his cell phone in the row behind you!), although this may only be a brief twist.

This framework has more recently been applied to describing bodily conduct with or without relation to (verbal) talk in a range of different settings, primarily around physical objects. For instance, Schegloff (1998) shows how body torque is coordinated with the linguistic progression of the turn-at-talk, and how participants, in and through their bodily arrangement, orient to possible completions of the ongoing TCU.

Artifacts and the Surroundings

The inclusion of physical artifacts and/in the surroundings is increasingly considered in multimodal analyses, in particular within professional or institutional settings, or both, and HCI. Ranging from “simple” written information in textbooks and on paper and classroom blackboards or whiteboards to complex, high-technological settings such as control rooms and airline cockpits, these studies show (a) how participants include and use tools when engaged in interaction, and (b) how these tools are used to structure the ongoing activity. *User-based design* is a special “applied” line of research, in which analyses of participants’ interaction with and around tools (in a broad sense of the word) are used as a basis for designing the tools themselves. For instance, the way in which computer screens (and other work-related artifacts) are physically positioned in a room structures the kinds of interaction that take place while interacting with the tools themselves. The study of ways in which people use technologies such as cell phones, online communication technologies, and GPS navigation systems, and broadly the field known as *workplace studies* (Luff, Hindmarsh, & Heath, 2000), will undoubtedly increase in the future, and, hopefully, feed back into design and engineering, and the development of (material/physical) products.

Sequentiality and Seriality

One of the basic assumptions of CA is that talk is sequentially organized. This is crucial for the establishment of intersubjectivity since the speaker, in and through the design, action, and timely (i.e., “sequential”) placement of a turn displays their understanding of the prior turn. For instance, some turns are so intimately tied together that the lack of a “second,”—that is, the “responsive” turn—is understood by the coparticipant to be *missing* and thus as accountable. Similarly, the beginning of a turn-at-talk displays the speaker’s orientation to the prior turn as being *possibly* complete. This includes primarily the study of *talk-in-interaction* and thus focuses on the verbal mode. However, the picture gets more complicated when several modes are taken into consideration (see, e.g., Mondada, 2008). Whereas the vocal mode is restricted to only one turn-at-talk at a time—that is, one (emergent) syntactic construction at a time—the visual mode is not constrained in the same way. While producing a turn-at-talk, one can produce several gestures and facial expressions, and move body and gaze simultaneously (the German *Koordination* tradition is a good example of how this is methodologically analyzed; see, e.g., Schmitt, 2007). This results in methodological challenges in terms of describing the *coordination* and *cooperation* of the various modes involved in human social interaction. Although it is unquestionable that human–human interaction relies on the intertwined co-occurrence of multiple modes (see, e.g., Goodwin, 2003, 2006), we still know little about how the different modes are coordinated, and how different modes contribute to the online meaning construction and production of social practices.

Conclusions and Current Trends

Since the 1980s, an increasing amount of research has described the complexity of *talk-and-bodies-in-interaction*, arguing that verbal talk and bodily conduct are finely coordinated within multifaceted physical surroundings to perform coherent social actions. This has served as an argument for extending the boundaries of a range of research fields working with “language,” including anthropology (Goodwin & Goodwin, 2005), linguistics (Mondada, 2006, 2007), and applied linguistics (Mori & Hayashi, 2006). Although the importance of

visual modalities in and for social interaction can hardly be neglected, it is less clear how the different modalities play together to perform what is essentially the scientific aim of CA: to describe recognizable social practices. This has probably been most systematically studied in relation to turn-taking organization. Within turn-taking organization, visual modalities (in particular gesture) have been shown to work systematically as a resource for projecting turn beginnings (Streeck & Hartge, 1992; Mondada, 2007) and possible completion of TCUs (Mondada, 2006). Undoubtedly, the description of social practices that are done (partly) in and through visual modes will have, or rather *continue* to have, a prominent position in the future. Systematic work is already in progress in relation to some basic findings of CA such as turn-taking organization (Hayashi, 2005; Schmitt, 2005; Mondada, 2006, 2007) and the organization of repair (Seo & Koshik, 2010). A relevant issue in this endeavor is a focus on the social practices that are performed in similar sequential positions through *different* multimodal resources (see Schegloff, 2009). This results in methodological challenges that remain to be further investigated. For instance, to what extent does gesture project (possible) turn completion compared to syntax and intonation? Is gesture “as strong” a resource as syntax in defining transition-relevant positions? What are the (interactional) boundaries between a “turn-at-talk” and an “action”?

Conversation Analysis and Other-Initiated Repair

TREVOR BENJAMIN AND HARRIE MAZELAND

This entry builds on the entry “Conversation Analysis and Repair Organization: Overview” by examining the organization of other-initiated repair. Excerpts (1) and (2) illustrate the two varieties, or trajectories, of other-initiated repair: those in which the repair proper is performed by the speaker of the troublesome talk (other-initiated *self-repair*) and by its recipient (other-initiated *other-repair*). The *trouble-source* (TS), the *initiation* (I), and the *repair proper* (R) are labeled in the transcripts:

(1) [other-initiated self-repair; CF:6938]

01 JEN: [((laughing))]
02 SAL: TS [is your man a medical] student?
03 JEN: I .hhh wha:t?
04 SAL: R is your man a medical student?
05 JEN: he's a dental student.

(2) [other-initiated other-repair; Schegloff, Jefferson, & Sacks (1977, p. 378)]

01 BEN: TS listen to the pigeons.
02 (0.7)
03 BIL: I+R [quail, I think.
04 ELL: [coo-coo::: coo:::
05 BEN: oh yeh?
06 (1.5)
07 BEN: no that's not quail, that's a pigeon.

Following a brief discussion of the positioning of other-initiations, this entry overviews these two varieties of other-initiation (self-repaired and other-repaired). It concludes with a remark on the relevance of repair for second language (L2) learning. For practical purposes, the excerpts presented are taken primarily from English data. The references cited throughout, however, include research on a wider number of languages.

The Positioning of Other-Initiations of Repair

Though they can become “displaced,” other-initiations of repair overwhelmingly occur as the first action following the possible completion of the turn constructional unit (TCU) which is or which contains the trouble-source (Schegloff, 2000). This adjacent positioning is explicable largely in terms of the organization of repair itself. First, by withholding their initiation until the troublesome TCU is possibly complete, and sometimes even a bit further, recipients provide the speaker with multiple opportunities to address the problem themselves. Second, adjacent positioning massively reduces the “search space” in which the trouble-source must be located (Schegloff et al., 1977). Cases like excerpt (3) provide evidence that participants work to achieve adjacent positioning.

DOI: 10.1002/9781405198431.wbeal1310

(3) [Schegloff (2000, p. 229)]

- 01 KEN: TS I'm always dreaming about walking down the aisle.
 02 and I can't stand [thinking about getting-
 03 ROG: I [getting hitched?
 04 KEN: R getting hitched.
 05 KEN: I can't stand thinking about it

In line 3 Roger indicates that he has trouble understanding Ken's use of the expression *walking down the aisle* by offering *getting hitched* as a candidate reformulation. Although he withholds during the trouble-source TCU (line 1), Roger positions this repair-initiation in overlap with Ken's turn continuation (line 2). Ken aligns by cutting off his turn and performing the repair proper (line 4) before resuming. Standard turn-taking practices are thus "over-ridden" to secure a "maximally adjacent" repair initiation (Schegloff, 2000; Benjamin, in press).

Other-Initiated Self-Repair

The most frequent cases of other-initiated repair are those in which the recipient indicates a trouble, but leaves the repair proper to the trouble-source speaker. These two actions—the initiation and the repair proper—form an adjacency pair through which the speaker and recipient collaboratively and interactively attempt to address the problem(s) at hand. Each part of this adjacency pair will be taken up in turn.

The Initiation

Recipients are provided with a substantial set of turn formats for initiating repair. These options vary primarily in whether and how they (a) locate what is causing the trouble (the *trouble-source*) and (b) delimit the nature of the trouble (the *trouble-type*), for example, as one of hearing, understanding, or accepting the trouble-source (Schegloff et al., 1977; Robinson & Kevoe-Feldman, 2010).

As noted, the adjacent positioning of other-initiations greatly aids in the identification of the *trouble-source*. Some formats, such as *what?* and *huh?* (see excerpt [1]; Drew, 1997), rely entirely on this sequential clue. Most formats, however, pinpoint a particular item in the trouble-source TCU, for instance, by repeating it (*May* ← *Mary* in excerpt [4]); replacing it with a *wh*-word (*he* ← *who* in excerpt [5]) or a candidate reformulation (*walking down the aisle* ← *getting hitched* in excerpt [3]); syntactically expanding off it (*city hall* ← *of Bristol* in excerpt [6]; see Hayashi & Hayano, in press); or deploying an incomplete repeat which locates the item as a gap to be filled (*to get into trouble* ← *you have no time* in excerpt [7]; see Koshik, 2002).

(4) [Field:2:1:1]

- 01 LES: TS Ma:y is: ill too:. she's had either a heart attack
 02 or a, slight stro:ke,
 03 MUM: I Ma:ry?
 04 (.)
 05 LES: R Ma:y.

(5) [CF:4504]

01 JOH: TS yeah he he went into the city ye- um: two days ago.
 02 GRE: I who.
 03 JOH: R Rick.

(6) [Field:2:1:1:1]

01 LES: TS a:nd em: (.) he's ↑been invited to a dinner at the city
 02 ha:l1 (0.2) we:l1 (.) Rimbold's=
 03 MUM: I =of ↑Bristol.
 04 (0.2)
 05 LES: R yes.

(7) [CF:4874]

01 B: TS besides for that I got no time to get into trouble.
 02 (0.9)
 03 B: hhh hhh
 04 A: I you have no [ti]:me_
 05 B: [hh]
 06 B: R to get into trouble.

The core identifying element may also be *framed* by repeated words or pro-form substitutions as in excerpt (8) (*Holly thinks he should do it* → *who does*; see also excerpt [12], line 3). Finally, when repair is initiated non-adjacently from the trouble-source turn, recipients sometimes aid in the identification task by signaling this “displacement,” for instance, with clausal formats such as *who's that* (cf. *who*) and *you mean the picture* (cf. *the picture*; Benjamin, in press; Egbert, in press).

(8) [CF:6952]

01 TOM: TS if Holly s- if Holly thi:nks he should do it that's it.
 02 TOM: .hhh [hhh]
 03 BIL: I [who] does?
 04 (0.3)
 05 TIM: R Holly.

The relationship between initiation formats and *trouble-types* is complex and has received considerable discussion in the literature. While the bulk of the trouble-type analysis resides with the trouble-source speaker (see the next section), the recipient can, through the selection of an initiation format, play an important role in this process. Robinson (2006), for instance, shows that unlike *huh?* or *what?*, the format *sorry?* is particularized to categorizing the trouble as the recipient's lack of hearing. There also seems to be a strong correlation between the prosodic/phonetic design of some formats and trouble-types. At least in German and English, falling terminal pitch on *wh*-word-based formats associates with underspecified reference, and rising terminal pitch with other types of problems (Selting, 1988; Egbert, Golato, & Robinson, 2009). Excerpts (5) and (7) illustrate this difference: *who* receives a further specification of the targeted reference (*he* ← *Rick*), whereas *who does?* receives a repetition (*Holly* ← *Holly*). Recipients can also deploy nonvocal methods for delimiting the trouble-type, for example, furrowed eyebrows to communicate lack of understanding, though this has not been studied systematically.

The Repair Proper

Faced with a recipient's repair initiation, a speaker is expected to repair the trouble as a next action. The solution they offer displays their analysis of the problem, or the analysis they are committing themselves to at this stage of the problem-solving activity (Pomerantz, 1984; Svennevig, 2008). A number of recurrent repair operations can be identified. First, the trouble-source speaker may repeat all (excerpt [1]) or part (excerpts [7] and [8]) of the trouble-source turn. While repetition may appear relatively straightforward—an efficient means of addressing auditory problems—analysis has shown that this repair operation is used in the environment of different trouble-types (Drew, 1997), and that the phonetic design of the repeat can index such differences (Curl, 2005). A second common repair operation is an elaboration on or further specification of the trouble-source, as discussed for excerpt (5) above. Third, when the initiation is a candidate understanding (as in excerpts [3] and [6]) or partial repeat (as in excerpt [4]), the typical repair operation is a confirmation such as *yeah* or corrective replacement, as in excerpt (4) above (*Mary* → *May*). The final repair operation to be mentioned here is rather different. Consider excerpt (9) below. Faced with the initiation *huh?*, the police desk modifies the preference structure of their question (the first version prefers a “yes” response, the revised version a “no”).

(9) [IND-PD]

- 01 POL: TS is she pregnant?
 02 CAL: I huh?
 03 POL: R she's not pregnant is she,
 04 CAL: I don't know.

There is an intimate relationship between other-initiations of repair and the organizations of preference and interpersonal alignment (Schegloff et al., 1977; Drew, 1997; Wu, 2006). Like turn-initial hesitations or hedges, other-initiations of repair halt the progressivity of the ongoing activity and can thus function as pre-rejections or pre-disagreements. Orienting to this possibility, speakers on occasion downgrade or, as in excerpt (9), even reverse the preference of the talk targeted for repair.

Other-Initiated Other-Repair

Participants can also repair items in the talk of others. Unlike simply initiating repair, performing the repair proper (i.e. *correcting*) involves a claim of greater authority or better access to the trouble-source. In excerpt (10) below, for instance, in substituting *hoog* ‘high’ for *laag* ‘low’ Leo claims superior knowledge regarding the value of the dollar. Such claims may be mitigated—note the uncertainty marker *I think* in excerpt (2)—and the speaker who is being corrected may either contest this claim—as in excerpt (2)—or ratify it—as in line 6 of excerpt (10).

(12) [international business call; MRD = Meredith, Dutch account manager; PIA = Italian agent]

- 01 PIA: (anne:hm::) (0.7) your u:H (0.3) so- sobistitute?
 02 (0.8)
 03 MRD: → my wha↑:ht?
 04 (0.4)
 05 PIA: (°eh [huh°) [(°yeah°)
 06 MRD: → [OH HehhUhe[h ·hH he:- .h you mean the person
 07 that will rePLA↑:ce me?
 08 (0.2)
 09 PIA: yeah:.

In lines 6–7, Meredith offers Pia a possible understanding of the trouble-source word (*sobistitute*), but does not engage in correcting its problematic form. The interactional achievement of a common understanding that furthers the progression of the sequence is given priority. Nevertheless, such sequences may display features that are relevant for the investigation of N–NN interaction. Schegloff (2000) and Wong (2000), for example, investigate “displaced” other-initiations and discuss the possibility that some instances may be typical of N–NN conversation, particularly those in which the NNS offers a sequentially preferred response based on a premature problematic understanding.

Schegloff et al. consider the possibility that the organization of repair—most notably, the “highly constrained occurrence of other-correction”—may differ in domains in which the socialization of the “not-yet-competent” is at stake. There, “other-correction is not so much an alternative to self-correction in conversation in general, but rather a device for dealing with those who are still learning” (1977, pp. 380–1). Macbeth (2004) develops this line of reasoning in his discussion of the relevance of other-correction in the classroom. Within the context of learning activities, other-initiation of correction and other-correction are deployed as devices for guiding pupils toward supposedly more competent uses of the forms, procedures, and content in the target domain. Correction is didacticized, and, as a consequence, is constrained differently from its use in noninstructional environments.

Similarly, participants in N–NN interactions may “transfer” and modify practices and formats from the organization of repair for initiating and pursuing language learning in noninstructional settings. Brouwer (2004), for example, analyzes practices that NNSs use for initiating learning activities focused on the pronunciation of words. The language expertise of the NSs is mobilized in a learning sequence in which the NNS is acting or treated as the learning party. Consider excerpt (14). S, a native speaker of Danish, has mentioned that all Danes carry around a special brand of rucksack.

(13) [Brouwer (2004, p. 93)]

- 01 B: ja det har vi ikk i Hol↓land at vi -alle ha:r (.)
 yeah we do not have that in Holland that we all have
 02 → d samme:: (0.4) øh ↑rygsa:k
 th same uh rucksack ((alternative pronunciation))
 03 (0.2)
 04 B: → ryg↑sak
 05 (0.2)
 06 S: → ↑ryg↓sæk.
 rucksack ((standard pronunciation))
 07 B: → rygsæk
 08 (0.3)
 09 B: → ↓så . . .
 so . . . ((continues))

B, an NNS of Danish, initiates a learning sequence by prosodically emphasizing and isolating the problematic item *rygsak* (lines 2–4). The NS responds by repeating the word using the standard pronunciation (line 6). The language learner then repeats this pronunciation (line 7), both as a kind of exercise and as a trial which the NS should monitor. After the learning sequence, the NNS returns to the activity that was temporarily put on hold. Note that, in this case, the correction produced by the NS is not about understanding but about the correct phonetic/phonemic form of a word which came up in talk. The participants are engaging in a side sequence for doing L2 learning with a focus on a particular aspect of linguistic form. Nevertheless, the learning sequence itself requires an appropriate understanding of what the NNS is doing when she is isolating, and prosodically marking a particular part of her turn and repeating it, or what the NS is doing when repeating this segment with an alternative pronunciation.

Conversation Analysis and Prosody

BEATRICE SZCZEPEK REED

The term *prosody* has varying definitions across language-related disciplines. In conversation analysis (CA) and its linguistic counterpart, interactional linguistics (Selting & Couper-Kuhlen, 2001), it refers to the “musical” aspects of speech, that is, pitch (intonation and pitch register), loudness, and time (syllable duration, speech rate, rhythm, and pauses); in addition, some writers include voice quality. Another term for prosody that is frequently used in linguistics is *suprasegmentals*. This term is based on the common linguistic distinction between articulation, which refers to the production of individual sounds or *segments*, and those areas of speech production that are above the level of individual sounds, that is, suprasegmental.

Pitch, loudness, time, and voice quality impact on spoken language in a variety of ways. *Loudness* is relevant, first, for the distinction between stressed and unstressed syllables, which is achieved, among other things, by brief increases and decreases in loudness (other features of stress are pitch and duration; see below). Stress is relevant to conversation in two ways. *Word stress* tells us which syllable in a multisyllabic word must be stressed. In English, this is invariable. More important for conversation is *utterance stress*, which describes the speaker’s choice regarding which words in a given utterance are to be made more prominent than others. This choice has significant implications for conversational meaning and information focus. Second, loudness becomes conversationally relevant when speakers increase or decrease their overall speaking volume for longer stretches of speech. Such a change is less relevant for the interactional role of an individual word, but represents a more global prosodic practice, with which speakers put longer utterances in relation to surrounding talk. For example, speakers may increase overall loudness when they are being interrupted, and thus show that they are the legitimate floor holders (French & Local, 1986). Overall loudness is typically reduced when speakers approach the end of their turn.

Time is conversationally significant, first, in terms of the time speakers take for the production of individual syllables, that is, *syllable duration*. In English, duration contributes to stress, together with loudness and pitch. This is relevant for word stress, but also for interactional purposes, in that syllables can be lengthened or shortened beyond their default pronunciation. For example, syllable lengthening becomes interactionally meaningful when speakers elongate syllables during expressions of appreciation (Szczepek Reed, 2006). Second, time is relevant when it comes to how fast or slowly conversationalists are speaking. *Speech rate* can be measured by counting the number of syllables, or sounds, per second. An example of the relevance of speech rate in interaction can be seen in Uhmann’s (1992) work on German conversations, which shows that high speech rate is associated, for example, with side comments and afterthoughts.

A third aspect in which time impacts on spoken language is *speech rhythm*, that is, the production of syllables at regular intervals of time. Speech rhythm in English, particularly British English, has a strong tendency toward “stress timing,” that is, stressed syllables are placed at roughly regular time intervals. Other languages and varieties, such as Singapore English and French, have a tendency toward “syllable timing,” where every individual syllable is perceived as a rhythmic beat. In all languages, speech rhythm is a highly perceptive category, and if we were to set a metronome against a speaker of British

2 CONVERSATION ANALYSIS AND PROSODY

English, they would soon be “off beat.” However, as listeners to spoken language, we have a strong tendency to perceive syllables as rhythmic. In CA, rhythm has been mostly analyzed for its role in turn taking (see below). Finally, time becomes relevant in spoken language when it comes to *pauses* and their duration. Silence can be highly significant for interaction. Local and Kelly (1986), for example, show that the phonetic features of pauses determine their role in conversation. “Holding” pauses, which are the result of glottal closure, are treated by conversationalists as indicating that a speaker is about to continue speaking. “Trail-off” pauses, in which the glottis remains open, are not necessarily interpreted in that way. In addition to the role played by pauses in conversation, they also have a direct impact on our perception of speech rate and rhythm.

Pitch is the prosodic feature that has received the most attention from students of language, in particular *intonation*. The term “intonation” refers to continuous changes in speech melody, which result in rising and falling *pitch accents* on stressed syllables. Many functions have traditionally been attributed to intonation, such as displaying grammatical structure, information focus, and a speaker’s emotions and attitudes. In CA, intonation has mainly been studied for its use in designing conversational turns as complete or incomplete (see below). Pitch, however, is also relevant in terms of changes in speakers’ overall pitch span. During the course of a conversation, speakers may change from an overall higher to an overall lower pitch register, for example, when they are producing a conversational aside (frequently produced with lower pitch register), or are preparing to say goodbye (frequently associated with higher pitch register). More specifically, Couper-Kuhlen (1996) has shown that conversationalists also differentiate between different types of pitch register changes. In certain interactional environments, copying a previous speaker’s high pitch register can be treated as repetition, if it is done relative to the next speaker’s own overall voice range; or as mimicry, and thus criticism, if it is done on an absolute scale, matching the previous speaker’s high pitch precisely.

In addition to these “musical” aspects of speech, the term “prosody” also comprises voice quality, especially in CA. In many other approaches to language, voice quality is regarded as outside the realm of linguistic inquiry, because it is not used to convey specific semantic meaning. However, research on the phonetics of conversation has shown that it is indeed an important factor when speakers negotiate interactional meaning. For example, Ogden (2004) shows the relevance of a variety of voice quality changes, such as creaky and breathy voice, for turn taking in Finnish.

CA, with its view on language as a resource for human interaction, has shown that prosodic features are relevant for the management of conversation. Particular attention has been paid to negotiating who speaks when, and for how long (turn taking), and the role of prosody for conversational actions, such as delivering good or bad news.

Regarding turn taking, prosody is one of the interactional modes used by conversationalists to negotiate issues of speakership and reciprocity. For example, in order to design a turn as finished, and thus as potentially signaling a place for others to come in, conversationalists typically bring it to completion in terms of its grammatical, pragmatic, and prosodic structure (Ford & Thompson, 1996). Out of these three, the prosodic aspect is the most locally flexible. Its form varies greatly with a speaker’s language, and indeed their linguistic variety. Different accents and dialects may use different prosodic signals to design turns as potentially complete. For example, Local, Kelly, and Wells (1986) show that in Tyneside English turn completion is achieved by a slowing down in speech rate toward the end of the turn, a sudden increase and decrease in loudness on the last stressed syllable, lengthening of that syllable, centralized quality on the final vowels, and either a step up or a drop in pitch on the last stressed syllable. Similar prosodic features are described in Local, Wells, and Sebba (1985) on London Jamaican English, and in Wells and Peppe (1996) on Ulster English.

In addition to these descriptions of the precise phonetic and prosodic nature of the final syllables of a potentially complete turn, Schegloff (1998) shows that in US American English, "pitch peaks" at the end of turns are interpreted by conversationalists as projecting an upcoming opportunity for turn transition. Similarly, Wells and MacFarlane (1998) show that speakers of West Midlands English treat final pitch accents as foreshadowing potential turn completion. In these researchers' data, however, the final accent is not a "peak," but a "valley." This finding confirms that prosodic features of conversation must be studied not only in the context of their immediate interactional environment, but also in the context of the linguistic variety in which they occur.

From the above-mentioned work on the precise prosodic nature of complete turns one must not conclude that every time a speaker designs an utterance in such a way this automatically "means" turn completion. Turn taking remains a process of local negotiation, and at each potential completion point—and in fact at other points, too—current speakers have the option of continuing, or not; and (potential) next speakers have the option of coming in, or not. Therefore, a further way of looking at the role of prosody for turn taking is in terms of its overall prosodic features.

For example, Couper-Kuhlen (1993) and Auer, Couper-Kuhlen, and Müller (1999) show that speakers of standard varieties of English typically continue the speech rhythm established by a previous speaker's turn in their own next utterance. In British and American English, this means that a next speaker must produce the first stressed syllable of his or her turn exactly at the moment at which a next beat is projected by the prior speaker's rhythm. Their research shows that conversationalists treat turn taking that does not follow this pattern as interactionally problematic.

The use of prosodic features from one turn to the next is not limited to speech rhythm. Under the term *prosodic orientation* Szczepiek Reed (2006) describes conversationalists' tendency to match or complement previous speakers' prosodic patterns in their own prosody. For example, next speakers frequently repeat prior speakers' intonation contours when they offer a response, such as an answer to a question, an agreement, or a return greeting. Both rhythmic integration and prosodic orientation show, first, that speakers are aware of each other's prosody; and, second, that prosody can function as a form of alignment between two turns, independent of the words being used.

Much research has been devoted to describing the role of prosody for specific conversational actions. For example, Freese and Maynard (1998) show that the prosodic design of delivering good news typically involves high pitch, a wide pitch span, increased loudness on key words, fast speech rate, and normal voice quality; whereas delivering bad news often involves low pitch, a narrow pitch span, syllable lengthening, breathy or creaky voice quality, decreased loudness on key words, and slow speech rate. However, as most studies demonstrate, very few conversational actions are accomplished exclusively through prosody. Instead, prosody is one of many resources of interaction that participants employ during an emerging conversation in order to negotiate actions and meaning. Other resources include articulation, lexis, grammar, information structure, and, if the interaction is face-to-face, gesture, gaze, and body posture, to name only the most obvious. By the same token, negotiating turn taking, actions, and meaning is not the only activity prosodic patterns are involved in. Prosody is also a language-specific cue for phonetic distinctions (for example, the role of syllable duration for distinguishing long and short vowels), lexis (for example, the role of loudness, pitch and duration for determining word stress), and syntax (for example, the role of pauses and intonation phrase boundaries for separating one syntactic construction from another). Furthermore, prosody is used as a cue for the display of affect and stance (Gardner, 2001). Thus, in everyday conversation prosody fulfills a multitude of functions, often simultaneously; but rarely are any of those functions fulfilled through prosody alone.

Conversation Analysis and Recipient Behavior

ROD GARDNER

Reciprocity is half of conversation. When a speaker is producing a turn at talk, there will be at least one recipient. Typically there is regular, frequent change of speaker, so the roles of current speaker or current listener change every few seconds. Non-talking participants, however, are not passive recipients. Their engagement is evident through nonverbal activities, such as gaze, head movement, gestures, smiles, eyebrow flashes, body orientation, and proximity to the speaker. They may also produce vocalizations, as well as, for example, laughter or sighs, which are not substantive contributions to the topical development of the talk, but which provide some indication of the kind of stance that the recipient is taking. Such tokens of reciprocity may supplement the visual cues for the current speaker; these expressions of affect, of claims of understanding, of agreement or disagreement, of changes in epistemic states, of a readiness to move toward other activities—not to mention the absence of such tokens—can tell the speaker a great deal about how their talk is being received. Indeed, as Heritage (1984, p. 335) noted, it is a mistake to treat these tokens as an undifferentiated set of “backchannels,” as “such treatments seriously underestimate the diversity and complexity of the tasks that these objects are used to accomplish.”

Such brief responsive utterances are often hard to “define,” in a dictionary sense. One claim we can make after thirty years of conversation analysis (CA) study of these tokens is that they are a complex, varied, and disparate group of objects. They have core uses, but these can vary according to their placement (what kind of turn at talk they follow and what follows them), their prosodic shape (whether they are falling, rising, or level in terminal pitch), and their timing (whether they overlap the prior talk, occur close to a completion point of unit of talk, or follow a gap of silence).

There follows an overview of some of the more common response tokens. For reasons of space, the focus is on English, though it is important to note that extensive work in a number of other languages exists. This is discussed briefly in the final section. The focus in the following four sections is on acknowledging tokens such as *Mm hm* and *Yeah*, epistemic tokens and newsmarkers such as *Oh*, activity shift tokens such as *Okay*, and an overview of assessments such as *Good*.

Continuers and Acknowledgment Tokens

One core group of brief response tokens is a closed set that briefly acknowledges the prior turn in various ways: *Mm hm / Uh huh*, *Mm*, *Yeah* (Jefferson, 1993), and *No* (Jefferson, 2002). *Mm hm* and *Uh huh* pass up the opportunity to take the next turn (Schegloff, 1982), thereby relinquishing the turn to the previous speaker. Sacks's lectures in the 1960s included some discussions on continuers such as *Uh huh*, for example in lecture 7, spring 1967; lecture 14, fall 1967; or May 24 lecture, 1971 (Sacks, 1992). However, the first attempt at a thorough analysis of response tokens was Jefferson (1981).

All excerpts quoted in this entry are taken from a dietary consultation at an Australian hospital. While a medical consultation is institutional talk with differences from ordinary

2 CONVERSATION ANALYSIS AND RECIPIENT BEHAVIOR

conversation in various ways, evidence so far suggests that response tokens are used in generally similar ways. In the first excerpt a dietician (DIT) outlines to a client (CLI) what will be covered in the following session.

- (1) [Diet:1A:1996:43]
- 01 DIT: >okay,= well ↑what ↓I'll do today.= just to outline thuh
 02 session is ↑jess ↓fin:d a little bit about
 03 your↑self↓= abo[ut ·hhh things like yihknow coking=
 04 CLI: [right,
 05 DIT: =of the mea:ls, who does tha:t↓= what y[uh do] during=
 06 CLI: -> [mm hm,]
 07 DIT: =thuh da:y↓ [·hhhhh] (.) bidda about what you ea:t,hh and (.)
 08 CLI: [righ';]
 09 DIT: =a (.) usual sort of in:ta:ke↓=
 10 CLI: -> =m[m hm,]
 11 DIT: [·hhh] and ↑then ↓we'll talk about yihknow triglyceride
 12 le-vel:s↓ [·hhhhh] a:nd wa:ys that (.) you could (.)
 13 CLI: -> [mmm hm,]
 14 DIT: =modify: the ↑di:et? (.) perhaps exer↑ci:se↓ ·hhh ↓tuh
 15 help riduce those le:vels of trigli[ceride;]= ↑oka:y?
 16 CLI: [°sure°;]

The dietician's talk consists of one long turn, made up of multiple turn construction units (TCUs). The three *Mm hm*'s from the client are placed close to points of utterance completion (such as *and a usual sort of intake* in lines 7 and 9). This reflects an understanding that the larger activity of outlining the session is still underway, so the right to take a turn at a transition relevant place (TRP) is passed up. Tokens that do this have been called "continuers," in the sense that the producer of the *Mm hm* is allowing space for the prior speaker to continue talking (Schegloff, 1982). *Uh huh* appears to be a variation on *Mm hm*. Note also that the terminal pitch direction of all three is slightly rising (indicated by the comma that follows them), which is typical for continuers. Note also that when the outline of the session ends, the client produces not a terminally rising *Mm hm*, but a falling *Sure*, which assents to the agenda for their meeting.

Mm typically has falling pitch. It works differently from *Mm hm* in rather subtle, but nevertheless distinctive ways. Its primary function is to acknowledge the prior turn rather than pass up the opportunity to take the next turn (Gardner, 2002). In excerpt 2, the dietician asks the client during the information-gathering phase of the consultation what kind of salad dressing he uses.

- (2) [Diet:1A:1996:521]
- 01 DIT: d'you know what type [↑it i:s?]= ↓o:r whether it's home=
 02 CLI: [·fhhhhhh]
 03 DIT: =[ma:de↓= ↓o:r.]
 04 CLI: [*e:::::hm:]::= Kra:f::t free?= o[r: Kraft light
 05 DIT: [Q:H-
 06 DIT: ↑good; so yer using a (.) a light one any[way.]
 07 CLI: -> [mm:..]
 08 (1.4)
 09 DIT: ↑grea:t ·hhhh and you ↑mentioned ↓sometimes having
 10 a desse:rt . . .

The client's answer is that he uses a low-fat salad dressing, an answer that provides new information for the dietician: her *Oh* in line 5 indicates an epistemic "change-of-state"

(Heritage, 1984). She positively assesses his answer with her *Good* in line 6, and formulates the upshot of his answer with *so you're using a light one anyway*. This effectively brings this question-answer sequence to a possible close, and the client produces a falling pitch *Mm*. What follows is a gap of silence of 1.4 seconds, and then another dietician assessment that closes this sequence, followed immediately by a new question. The client's neutral *Mm* acknowledgment of the dietician's turn is not a continuer, but an acknowledgment that evinces that there is nothing to add to the answer he had already given (Gardner, 2002).

Yeah (or *Yes* and other variants) is probably the most frequently used of all response tokens in English conversation (Drummond & Hopper, 1993; Jefferson, 1993). It has similarities to *Mm*, in that it primarily acknowledges the prior speaker's turn, but through its positive polarity it often can be seen as doing more than mere acknowledging, by aligning and—depending on the nature of the prior talk—confirming or agreeing with what the prior speaker had said, as well as being more likely to be followed by more talk by the same speaker (Jefferson, 1993). It is also used as an answer to polar (“yes/no”) questions. In excerpt 3, there are five *Yes/Yeah*'s. The first of these is an answer to the question, *Do you like tomato and that sort of thing*. The consultation has entered the phase in which the dietician is providing the client with advice about how to improve his dietary intake.

- (3) [Diet:1A:1510:34'00"]
 01 DIT: d'jou like toma:to and ↑that sort of thi[ng you can=
 02 CLI: -> [yes::.
 03 DIT: =have on [biscuits.]
 04 CLI: [mm hm,]
 05 CLI: mm [hm̩
 06 DIT: [·hhh tha:t's something that's a bit more filling:̩=
 07 and it [looks more uh- [interesting̩
 08 CLI: -> [yes. [↑mm::.
 09 CLI: [Mm::.]
 10 DIT: [·hhhh] u:hm but it's[: still a reasonable snack in=
 11 CLI: [that's right.
 12 DIT: =betwee[:n. ·hhhh [↑e:ither ↓th]at or another p-piece of=
 13 CLI: -> [yehs; [uh huh,]
 14 DIT: =fruit like yuh sai[:d,
 15 CLI: [mm hm,
 16 DIT: u:m ·hh- >or yuh might even wanna< have a sma:ll
 17 yihknow half a sa:ndwich;= or something [like] uh- a=
 18 CLI: [mm::.]
 19 DIT: s-salud [or something like that̩ ·hhhh just tuh: fill=
 20 CLI: -> [ye:ah,
 21 DIT: =up so that yuh not gonna snack on;
 22 CLI: -> yehs.=

The second *Yes*, in line 8, is an acknowledgment token, which aligns through agreement with the dietician's judgment that tomatoes (and similar foods) are *something that's a bit more filling*. Furthermore, unlike an expert opinion, this is something that falls within the client's personal experience, which displays agreement in a way that the neutral acknowledgment *Mm* would not do. The remaining *Yes*'s in lines 13, 20, and 22 similarly follow assessments or suggestions with which the client aligns. Note that whereas a positive *Yes/Yeah* can be seen to align with the prior turn, the *Mm* that follows *You might even want to have a small, you know, half a sandwich* declines to align or agree—or to disalign—with this suggestion. A *Yeah* could be seen as agreeing that “half a sandwich” is what he wants, whereas the *Mm* leaves such agreement unstated.

4 CONVERSATION ANALYSIS AND RECIPIENT BEHAVIOR

In this third excerpt, there is also a stronger expression of agreement, *That's right*, in line 11. Note that this follows the more noncommittal *Mm* in line 9. Both respond to the dietician's *and it looks more, uh, interesting*. *That's right* has the effect of upgrading an initial neutral acknowledgment to an agreeing one, but more strongly than a *Yes* would.

Epistemic Tokens

A second set of response tokens is epistemic. These can be expressions of receipt of new knowledge (*Oh*), of understanding (e.g., *I see*), to mark something as news (e.g., *Really*), or of acknowledging epistemic connections between two actions (*Right*).

Oh has been the subject of a series of publications by Heritage (e.g., 1984). The core use of *Oh* is to claim a change in epistemic state: It marks the prior talk as containing information that the recipient did not have before. There was an *Oh* in excerpt 2, reproduced here as excerpt 4.

- (4) [Diet:1A:521]
01 DIT: d'you know what type [[↑]it i:s?]= ↓o:r whether it's home=
02 CLI: [·fhhhhhh]
03 DIT: =[ma:deɪ= ↓o:r.]
04 CLI: [*e:::::hm:]::= Kra:f:t free?= o[r: Kraft light
05 DIT: -> [Q:H-
06 DIT: [↑]good; so yer using a (.) a light one any[way.]
07 CLI: [mm:.]
08 (1.4)
09 DIT: [↑]grea:t ·hhhh and you [↑]mentioned ↓sometimes having
10 a desse:rt

Heritage's work suggests that the information that the client uses a light salad dressing was not within the dietician's domain of knowledge, and she further marks this as positive with her subsequent assessment *Good*. Such *Oh*'s are reproduced in response to informings, or to answers which include informings, or counter-informings contradicting some earlier informing: They are an archetypal expression of "coming to see something" (Heritage, 1984, p. 337) that one had not seen before.

Brief listener responses can also claim simple understanding (such as *I see*), or strong agreement (*That's right*). *Right* can be used in the sense of 'Correct' (a widespread North American English use), but in British and Australian use it regularly goes beyond that to respond to complex prior talk in which the speaker is constructing "a progressively emerging epistemic construct" (Gardner, 2007), such as an explanation or advice giving.

Activity-Shift Tokens

A third major group of response tokens includes *Okay* (Beach, 1993; Pillet-Shore, 2003) and *Alright*. These project a readiness to move to a new activity or matter. In the dietetic interview (as in many medical consultations and other kinds of interviews), *Okay* is mostly found in third position following a question and answer. In such cases there is usually an agenda of questions, and the *Okay* is sequence-closure relevant, proposing a move to the next question. Excerpt 5 illustrates this. After summarizing his daily diet, the client is now responding to a series of questions from the dietician to record in more detail his daily

intake. In lines 2 and 4, the dietician asks the client what kind of toast he eats at breakfast, to which the client replies that it is *brown* (line 5).

(5) [Diet:1A:1996:366:9'50"]
 01 (1.5)
 02 DIT: and type of ↑toast? would it be:
 03 CLI: u:::[:::~::~:hmm]
 04 DIT: [a white toa]st, or a brow:n toast?
 05 CLI: brown.=
 06 DIT: =brown.
 07 CLI: °wholemeal (.) (sort of bread,)°?
 08 (0.2)
 09 CLI: °(bread).°
 10 (0.7)
 11 DIT: -> °okay°?
 12 (1.6)
 13 DIT: -> °okay? ·hhh and you mentioned butter.= would that be
 14 butter or ma:rgari[:ne.
 15 CLI: [°>margarine<.
 16 DIT: -> it would bi margari:ne,= o↑kay?
 17 (1.4)
 18 DIT: ↑and what about between your breakfast and your
 19 lunch.

The dietician seeks confirmation of this in line 6 by repeating *brown*, before the client elaborates to say that it is *wholemeal*. The dietician accepts this as a sufficient answer by proposing to close this question–answer sequence with her *okay* in line 11. This is followed by a 1.6-second silence and then another *okay* at the beginning of line 13. During the silence, she writes his answer on a form she has in front of her, so the second *okay* can be understood not as a second closing of the prior sequence, but to show that her form filling is completed, and she is ready to move on to the next question. She then does so, and he gives a one-word answer, *margarine*. She confirms his answer in line 16, followed by another sequence-closing *okay*, before moving on to the next sequence. So these *Okay*'s can be seen to be marking boundaries between question–answer sequences in a series of questions in a set agenda.

Alright and *Right* (the latter with a different function to the epistemic *Right* discussed above) can also be used to propose a shift in activity, but they, and especially *Alright*, appear to be used with higher-level activity shifts, such as ending more extended sequences.

Assessments

Assessments form a much more open group of often brief responsive utterances. Any expression that makes some positive or negative evaluation of a prior turn, expresses an affect reaction, or expresses a judgment can be an assessment (see Goodwin & Goodwin, 1987). They include expressions such as *Great* or *How awful*, but also longer utterances, for example *That's great, that's been very helpful*. The reason for including assessments in a summary of recipient talk is that they are frequently brief responses to a prior turn, though it should be noted that assessments can also be first turns in a sequence. Excerpt 6 shows some recipient assessments.

- (6) [Diet:1A:1996:105:4'00"]
 01 DIT: ·hhh (0.4) °an:d (.)↑yuh've° (.) got any diabe:tes

 12 DIT: -> [THA(H)T'S G_OO(H):D.]
 13 DIT: -> \$glad tuh hear it.\$ ·hhh ↑an: what ↓about
 14 medica:tions.

In this excerpt, the dietician produces a series of assessments of the client's answers to her questions about his medical condition and its effect on his diet. The client claims to have been *very lucky* (itself an assessment), to which the dietician responds with an emphatic *Good* and *that's g-* (the start of 'good' or 'great?') in line 9, and a further loud *That's good* in line 12, and *Glad to hear it* in line 13.

Assessments perform a rich and complex range of actions beyond the kind presented in excerpt 6. Antaki, Houtkoop-Steenstra, and Rapley (2000), for example, show how assessments can be used in conjunction with activity-shift tokens such as *Okay* to indicate successful completion of question-answer sequences in institutional talk, particularly when these have required more work than usual to bring them to conclusion. Low-grade assessments, in contrast, have been shown in some situations, such as home-care visits in Denmark and Sweden (Lindström & Heinemann, 2009), to close routine tasks that have been adequately performed as "good enough" for the occasion.

Cross-Institutional, Multimodal, Crosslinguistic, and Cross-Cultural Issues

The discussion so far has been about English, and the examples are taken from a single, medical institutional setting. While the evidence we have points to these examples being representative of the use of response tokens in English, there remain a number of unanswered questions about issues that have not been addressed here: What is the role of the visual in recipient behavior? What differences are there between ordinary conversation and various institutional settings, such as legal, media, educational, business, or political? What differences will we find across languages and cultures?

There has been relatively little research into recipient behavior multimodally, though this is increasing (e.g., Barske, 2009), as it is for various institutional settings (e.g., Jones, 2001, for medical settings). Stivers (2008), however, shows that visual responses such as nods and vocal continuers attend to different aspects of storytelling: The former affiliate with the storyteller's stance, while the latter align with the emerging line of the story. Ruusuvuori and Peräkylä (2009) demonstrate how facial expression works alongside vocal assessments, often preceding them, to display participants' stance to the storytelling.

There is very little on child language (e.g., Filipi, 2007) or second language speaker talk (e.g., Wong, 2000). There is a more substantial literature on response tokens in other languages, notably Japanese. While all languages and cultures would appear to have a place for response tokens, there are differences. In Japanese, for example, response tokens, known in Japanese as *aizuchi*, occur more frequently than in English or other languages that we

know about (Kita & Ide, 2007). It has been proposed that this relates to the grammar of Japanese, which is a verb-final language, with grammatical particles frequently also occurring utterance-finally. These factors make it more difficult to predict where an utterance will come to completion. To compensate, Japanese speakers tend to produce *aizuchi* during utterance-internal grammatical boundaries, such as after the subject, object, or an adverbial phrase. That being stated, on the evidence we have so far, languages that have been studied appear to have response tokens of a broadly similar type to English, though with some differences. (See, e.g., Xudong, 2008, for Chinese; Heinemann, 2005, for Danish; Mazeland, 1990, for Dutch; Keevalik, 2010, for Estonian; Sorjonen, 2001, for Finnish; Betz & Golato, 2008, and Golato & Fagyal, 2008, for German; Young & Lee, 2004, for Korean.) This is not surprising, as recipients of talk—who are at least half of talk-in-interaction—need some way to express how they are responding to the talk that they are hearing.

Conversation Analysis and Repair Organization: Overview

BARBARA A. FOX, TREVOR BENJAMIN, AND HARRIE MAZELAND

Introduction

Repair is the cover term for a range of practices, found in all languages that have been studied, by which trouble of all sorts is managed. Whether the trouble arises from problems with speaking, hearing, understanding, or, potentially, agreement, repair practices exist which can attend to it within just a few turns of the source of the trouble. Repair provides a locally managed, interactionally organized, procedural architecture through which participants preserve intersubjective understanding (Schegloff, 1992).

Although there had been experimental studies on disfluencies in talk, and on requests for repetitions, clarifications, and so forth, the groundbreaking study by Schegloff, Jefferson, and Sacks (1977) was the first to treat these various phenomena as belonging to a single organization, for which the term *repair* was introduced. In their paper, the authors describe the temporally ordered opportunities for repair in naturally occurring talk-in-interaction, and specify the basic mechanisms which underlie them.

In describing repair it is necessary to make a few basic distinctions. One is that repair typically happens in two phases: first, repair is initiated, that is, some trouble is indicated; second, the repair itself is performed, that is, the trouble is attended to or “fixed.” We thus speak of *repair initiation* and the *repair proper*. Given that there are two phases of repair, it is necessary to distinguish which participant engages in each phase. The organization of repair references only two parties: the speaker (*self*) and any other participant (*other*). Thus, for example, self can both initiate and perform the repair proper, or other can initiate and self can perform the repair proper, and so on, in all possible combinations.

These combinations, however, are not randomly distributed in talk. Some are tremendously more frequent than others and have a larger set of opportunities dedicated to them. Analysis has revealed that opportunities for self to initiate, as well as to perform the repair proper, outnumber opportunities for other to initiate or to perform repair; in addition, opportunities for self to initiate precede opportunities for other to initiate. And lastly, even when others initiate, they typically (a) refrain from producing the repair proper, leaving an opportunity for self to accomplish the repair, and (b) delay their initiation, providing further opportunities for self-repair. These facts taken together suggest a preference for self-repair over other-repair.

It should be kept in mind that repair is more general than “correction,” involving on many occasions utterances which have no perceivable “error” in them. In fact, in many instances, especially for self-initiated self-repair, the motivation for the repair cannot be discovered. However, in all cases repair delays the progressivity of the turn or sequence, in that rather than producing the next item or action due, one of the parties initiates repair.

Opportunities for Repair

Opportunities for the initiation of repair are ordered with respect to the trouble-source. This section provides a brief overview of these possibilities. For expository reasons we will give examples from English, which is also the language on which most groundbreaking work on the organization of repair was conducted. This is not to imply, however, that the linguistic form of repair actions is identical in talk-in-interaction across languages.

The first position in the *repair-initiation opportunity space* arises in the same turn construction unit (TCU) in which the trouble occurs. Consider excerpt (1):

(1) [at the farmhouse]

01 LAU: she gave her best friend and her husband
 02 a surprise birthday party for their
 03 → birthda- fiftieth birthdays and she
 04 wants us to just forget about hers.

Laura initiates repair in the final syllable of what is projected to be *birthdays* in order to insert the modifier *fiftieth*. This illustrates *same-turn self-repair*. The speaker of the trouble-source initiates and accomplishes repair within the same TCU in which it occurs. While significantly less common, self-initiated other-repair is also possible in this position, for example, in word searches.

The next opportunity arises at the possible completion of the TCU in which the trouble-source occurs. *Transition space repair* is also self-initiated self-repair. Excerpt (2) illustrates this:

(2) [Field:X(C):1:1:1]

01 MUM: Cyd rang this evening.
 02 MUM: → Cyd Arnold,
 03 (. .)
 04 LES: how is sheu?

Mum comes to a place of possible completion with *evening* and then initiates and accomplishes repair with a next utterance, in the transition space of the initial TCU.

The third systematic opportunity for initiating repair—and the first for “other”—arises in next position after the trouble-source turn (Schegloff, 2000). Excerpt (3) illustrates *other-initiated self-repair*. *Other-initiated other-repair* is also possible.

(3) [CF: 6938]

01 JEN: [((laughing))]
 02 SAL: [is your man a medical] student?
 03 JEN: → .hhh wha:t?
 04 SAL: → is your man a medical student?
 05 JEN: he's a dental student.

In overlap with Jen's laughter, Sally asks Jen about her new boyfriend. Jen initiates repair with *wha:t?* and Sally then repeats her utterance, performing the repair proper.

Following next turn is another opportunity for self-initiated self-repair, referred to as *third position repair*. In excerpt (4), the recipient produces a turn which displays an understanding of the trouble-source turn which the original speaker finds problematic.

(4) [Field:X(C):1:1:1; Leslie has bought Mum some biscuits]

01 LES: it's e-well I don't know that they are very good heh
 02 he[h
 03 MUM: [what are they then,
 04 (.)
 05 LES: shortbread.hh
 06 (0.4)
 07 MUM: → no I mean what ma:ke,
 08 (0.4)
 09 LES: oh:: hum (1.0).hhh well some Scottish make,

Leslie's answer, *shortbread*, displays an understanding of Mum's question as asking about the biscuit's type (cf. oatmeal). Mum initiates repair to "correct" Leslie's understanding. Third position repairs exhibit a highly recurrent format: a repair initiation (typically "no"), an agreement/acceptance (e.g. "I know"), a rejection (often "I don't mean X"), and the repair proper (often "I mean" plus a contrast, reformulation, or, as in excerpt [4], specification; see Schegloff, 1992).

In contrast to excerpt (4), self can also initiate repair following minimal responses. In excerpt (5), Hannah initiates and repairs *paintings* after she has reached possible completion and her recipient has responded with *mhm*.

(5) [SBL:1]

01 HAN: And he's going to be making his own paintings.
 02 BEA: Mhm
 03 HAN: → And- or I mean his own frames.

Despite its positioning, this type of repair, known as *third turn repair*, is more similar both in form and in "motivation" to transition space repair than to third position repair: The repair arises from the original speaker entirely and not from the recipient's displayed understanding (see Schegloff, 1997).

These positions—same-turn, transition space, next position, and third position—provide a set of ordered opportunities for addressing troubles in talk-in-interaction. They are organized relative to their distance from the trouble-source in an order that favors self-initiation over other-initiation and self-repair over other-repair. The entries on "Conversation Analysis and Self-Repair" and "Conversation Analysis and Other-Initiated Repair" provide more detailed research results for each of these areas. They also discuss language-specific patterns for the design of self-repair and the relevance of repair in learning and learner interactions.

Conversation Analysis and Second Language Acquisition: CA-SLA

SIMONA PEKAREK DOEHLER

CA, SLA, and CA-SLA

Conversation analytic research on second language acquisition (CA-SLA) has emerged relatively late in the history of both CA and SLA. This is largely due to the historic development and the analytic focus of the two fields of research. On the one hand, ethnomethodological CA originated as a critical approach to society concerned with the local production of social order; it was not designed to address issues of learning or development. On the other hand, SLA research has traditionally been focused on the learner's internal cognitive processing of linguistic forms; it has paid only limited attention to the social-contextual dimensions of the learning of a second language (L2) (but see Hatch's, 1978, early statement). Yet, since the 1990s, the SLA scientific landscape has undergone a notable shift toward more socially, socioculturally, and sociocognitively oriented approaches, involving an increased awareness of the contingent, contextual, adaptive, and hence non-linear nature of learning. CA research has played a major role in this development. In a much-quoted programmatic statement, Firth and Wagner (1997) have outlined the basic principles of what was later to become CA-SLA, calling for a "significantly enhanced awareness of the contextual and interactional dimensions of language use" (p. 286). Their argument has triggered a critical debate between cognitive and socially oriented SLA researchers (see *Modern Language Journal*, 1997, 81[3], 2007, 91[5]), and has provided major impulses for CLA-SLA research ever since.
